# INDEX TO VOLUME CXVI.

**Abbott, S. W.** Recent progress in public hygiene, 305; the value of public health measures to the State, 579.

**Abdominal Surgery.** The intestinal suture, Newell, O. K., 1, 10; a case of laparotomy for recent adhesions of the intestines to the abdominal parietes: recovery, Gay, G. W., 25, 29; pistol-shot wound of the abdomen treated by laparotomy and suturing the intestines, Kinloch, R. A., 595; death from post-partum hemorrhage involving the liver, stomach, peritoneal mesenteric veins, intestines, and kidneys: laparotomy, nephrectomy: death on the fifteenth day: autopsy, Kean, W. W., 508; drainage of abdomen in tubercular peritonitis, Homans, J., 554; laparotomy for pus in the abdominal cavity and for peritonitis, Irish, J. C., 577.

**Abrams, A. E.** The treatment of diseases of the ear by the general practitioner, 622.

**Abcesses.** A case of peri-nephritic abcess, following typhoid fever: operation: recovery, Devine, W. H., 422; abcess of the kidney from obstruction to a ureter, Blake, J. G., 549, 552.

**Accidents.** Rosinoline disaster, Sparhawk, C. W., 477; appliances useful in such an emergency (railroad accident), Ernst, H. C., 479; injuries to life back in railroad accidents, Gerry, E. P., 468, 477.

**Agnew, D. H.** The medico-legal aspect of cranial and thoracic wounds, 524.

**Alcohol.** Two cases of chronic alcoholism, Gorton, W. A., 201, 209; the influence of alcohol on the digestive functions in the normal and in the pathological state, 457.

**Alexander's Operation.** A case of Alexander's operation, Swift, J. B., 421, 427.

**Alimentation.** Some cases of phthisis: marked improvement under general treatment, with special reference to alimentation, Shattuck, F. C., 580.

**Amputations.** Amputations for joint-diseases when lung tuberculosis co-exists, Richter, L. S., 528.

**Anatomy.** Recent progress in anatomy, Dwight, T., 229; an anomalous arrangement of the veins of the neck, Pinkham, J. G., 262; floating kidney, Dwight, T., 318; surgical anatomy of the esophagus, Richardson, M. H., 524.

**Anæsthesia.** Local anæsthesia in dental surgery, 98; is the danger from post-partum hemorrhage increased by the use of anæsthetics during parturition? Barker, F., 125, 130; the proper selection of ether or chloroform as an anæsthetic, Gerster, A. F., 432; the primary anæsthetic stage of ether, Packard, J. H., 537.

**Aneurisms.** Case of aneurism of the innominate, Lyman, G. H., 235, 401; the aneurismal distasia, Shmely, J., 405; the treatment of aneurisms, 410; aneurism of the left subclavian artery for the cure of which three methods of treatment were employed: death, Richardson, T. G., 527; femoral aneurism cured by elevation and flexion of the limb, Richardson, T. G., 528; a case of aneurism of the abdominal aorta, Dana, I. T., 573.

**Anthony, A. V. S.** Arsenical wall-papers again, 295.

**Antipyrine.** Anæsthesia, as an analgesic, 534.

**Antifebrin.** Eisenhart, 341.

**Antisepsis.** An economical method of preparing antiseptic gauze, Gerster, 538.

**Antiseptics.** The use of antiseptics in obstetric practice, Richardson, W. L., 73, 78; antiseptics in obstetrics, 95; iodiform not an antiseptic, 241.

**Apartment-Houses.** The hygiene of apartment-houses, 457.

**Apostoli.** On a new method of treatment of chronic metritis, and especially endo-metritis, by the intra-uterine chemical galvanocautery, 370.

**Army.** Report of the surgeon-general of the army, 120.

**Army and Navy.** The pay of medical officers in, 241.

**Arsenic.** Poisonous arsenical wall-papers, Chadwick, J. R., 129, 130; arsenical wall-papers, 141; the discussion on arsenic at the Suffolk District Medical Society, Lee, C. T., 198; arsenical wall-papers again, Anthony, A. V. S., 295.

**Asch, M. J.** A case of stenosis of the larynx treated by division and systematic dilatation, 639.

**Ashkey, G.** Distance-union of nerves and tendons and some applications of animal grafts, 413.

**Atkinson, I. E.** Forms of typhoid fever simulating remittent malarial fever, 637.

**Axillary Lumps.** Williams, E. T., 222, Boxall, R., 146, 366.

**Ayer, J. B.** Ovarian cystoma of rapid growth, causing severe peritonitis and intestinal obstruction, 209; the treatment of chronic uræmia, 314, 380; empysematous peritonitis from abscess of the liver, 376; third attack of scarlet fever: remarks upon the recurrence of eruptive diseases, 407.

**Bacteria.** In ice and their relation to disease, Prudden, T. M., 333; phagocytes and bacterial invasion, 485; growth of pathogenic organisms in water, 537.

**Baker, L. W.** Mental disturbances following the cessation or diminution of epileptic attacks under treatment, 463.

**Baldness.** Hints as a cause of baldness, 435.

**Barker, F.** Is the danger from post-partum hemorrhage increased by the use of anæsthetics during parturition? 125, 130.

**Bean, C. E.** A case of recurring laryngitis hemorrhagica, 615.

**Bearsley, G. F.** Physical training in elementary schools, 197.

**Beer.** The health of beer-drinkers, 67.

**Bell, A. N.** Sanitation of emigrant ships, 589.

**Bellamy, E.** Symmetrical gangrene (Raynaud's disease) following varicella in a child aged four causing death on the fourth day, 489.

**Bendall, H.** Tobacco amblyopia, 139.

**Bergson's method of treating phthisis.** Bruen, E. T., 611; clinical notes on Bergson's method of treating phthisis, Shattuck, F. C., 612.

**Beri-Beri.** A brief account of outbreaks in this country and of some recent cases not hitherto reported, Shattuck, F. C., 353; beri-beri again brought to New York, Shattuck, F. C., 462; was it beri-beri? Stevens, R. B., 374; a case of beri-beri, Fou, oy, H. J., 558.

**Berlin.** Letter from, 616.

**Bibliography.** Adams, B., the emacipation of Massachusetts, 216; Amory, R., a treatise on electricity and its applications to therapeutic and surgical treatment in disease, 40; Army, report of

the surgeon-general of the army, 120; Atkinson, F., elements of static electricity, 336; Bernard, de l'aphasie et de ses diverses formes, 532; Boston Health Report for the year 1896, 230; Brown, F. H., the Medical Register for New England, 335; Collis, A., on fevers, their history, etiology, diagnosis, prognosis and treatment, 215; Cupples, G., report of the Special Committee on treatment, Texas State Medical Association, 642; Eichhorst, H., handbook of practical medicine, 140, 214; Ferriér, D., the functions of the brain, 533; fifteenth annual report of the Local Government Board, 456; Finlayson, J., clinical manual for the study of medical cases, 214; Fox, L. W., a compend of diseases of the eye: including refraction and surgical operations, 533; Gowers, W. R., a manual of diseases of the nervous system, 335; Harvard College, annual reports of the President and Treasurer of Harvard College, 1887-1896, 129; Heitzmann, C., anatomy descriptive and topographical in 625 illustrations, 617; Macelean, W. C., diseases of tropical climates, 215; Massachusetts, fourth decennial census, 269; Massachusetts General Hospital and McLean Asylum, seventy-third annual report of, 510; Mitchell, S. W., wear and tear, or hints for the over-worked, 215; Morris, H., surgical diseases of the kidney, 215; Morris, R. T., how we treat wounds to-day, 215; Morrow, F. A., drug eruptions: a clinical study of the irritant effects of drugs upon the skin, 408; Morton, A. S., refraction of the eye, its diagnosis and the correction of its errors, 456; Murrell, W., massage as a mode of treatment, 209; New Jersey, tenth annual report of the State Board of Health, 432; Parvizi, T., the science and art of obstetrics, 642; Powell, R. D., diseases of the lungs and pleura, including consumption, 369; Prentice, a treatise on simple and compound ophthalmic lesions, their refraction and dioptric formulae, 533; Prichard, N., handbook of diseases of the ear, 64; Ross, J., handbook of the diseases of the nervous system, 64; Ross, J., on aphasia: being a contribution to the subject of the dislocation of speech from a cerebral disease, 204; Sillie, A., and Maish, J. M., the National Dispensary containing the natural history, chemistry, pharmacy, actions and uses of medicine, including those recognized in the pharmacopœia of the United States, Great Britain, and Germany, with numerous references to the French codex, 140; Strümpell, A., a text-book of medicine for students and practitioners, 216; Snelgrove, hemorrhagic uterine: etiology, diagnosis, treatment, 411; United States Navy: annual report of the surgeon-general, 193; Vaillard, L., manuel pratique de la vaccination animale, 436; White, J. C., dermatitis venerea: an account of the action of several irritants upon the skin, 401; Winckel, F., diseases of women, 407; Wood, H. C., nervous diseases and their diagnosis, 422; Worcester, A., monthly nursing, 407; Ziegler, E., a text-book of pathological anatomy and pathogenesis, 405.

**Bigelow, E. H.** A case of abdominal pregnancy, 578.

**Bigelow, H. R.** Erosions of the cervix uteri, 428.

**Biggs, H. M.** History of an epidemic of dysentery at the alum-house, Blackwell's Island, New York, 210; presentation of the cord and nerves in a case of alcohol paralysis: multiple neuritis, 282.

**Bill Salts.** The value of the bile salts when used in conjunction with emulsions of cod-liver oil, Harb, H. A., 273.

**Billings, J. S.** Methods of literary research, 563; methods of research in medical literature, 597.

**Billington, C. E.** Local treatment in diptheria, 281.

**Biography.** Bandl, L., 123; Bird, J. G., 621; Caswell, E. T., 392, 438, 462; Courty, 238; Dyer, E., 172; Field, C. C., 148; Fisher, L., 248; Flint, A., 262; Flint, J. S., 392; Fox, W., 514; Fulton, J. B., 216; Gallard, 228; Gates, E. S., 189; Gordon, W. A., 100; Hick, W., 257; Howe, E., 72, 100; Hudson, E. D., 400, 620; Johnson, W., 645; Jones, A., 392; Knight, L. M., 148; Leonard, W. B., 464, 568; Lieberkühn, 337; Magee, A. B., 124; Magin, F., 280; Marshall, J. A., 241; Metcalf, T., 340; Parks, L., 248; Pratt, G. F., 438, 440, 462; Peckham, F. H., 200; Perry, W., 72, 100; Rochester, T. F., 636; Schroeder, 244, 288; Stone, S. E., 122, 124; Small, H. N., 24; Smith, J. V., 392; Thorndike, W., 127; Vulpian, 524, 621; Wakeld, J. F., 72; Warren, G. A., 516; West, J. T. O., 124, 144; Youmans, E. L., 97.

**Birdsall, W. R.** A case of progressive muscular atrophy, with bulbar symptoms, 12.

**Birdsall, W. R. and Weir, E. F.** Report of a case of sarcoma of the brain: occipital lobe, causing hemianopsia: removed by operation, 420.

**Bishop, E. T.** Removal of foreign bodies in the esophagus, etc., 270.

**Bismuth.** Poisoning by dressings of substrate of bismuth, Dalché, M. F., 469.

**Bladder.** The exploration of the bladder by the supra-pubic method, Dennis, F. S., 461; supra-pubic cystostomy for other purposes than the removal of calculus, Packard, J. H., 482; supra-pubic cystostomy and other operations for the removal of vesical calculi, 486; tumors of the bladder, Davis, G. W., 577.

**Blake, J. G.** Abscess of the kidney from obstruction to a ureter, 549, 552.

**Blanchard, B. S.** Contracted fingers, 245.

**Blodgett, G. W.** Poisoning by ivy, 622.

**Boardman, W. E.** The treatment of fissured nipple, 579.

**Bolles, W.** Case of bronchorrhœa complicating labor, 11.

**Borthea.** Three cases of suppurative of the frontal sinus, 69.

**Bowditch, V. Y.** The use of strophanthus hispidus in heart diseases, 455, 367.

**Boxall, R.** Milky tumors of the axilla, 146; axillary lumps, 366.

**Bradford, E. H.** A case of recurring intestinal obstruction: right lumbar colotomy: recovery, 160; subperitoneal amputation a hip-joint after hip-disease, 180, 182; a case of McEwen's operation for radical cure of hernia, 575; cases of orthopedic surgery, 376.

**Bradford, E. H. and Gay, G. W.** Two cases of compound depressed fracture of the skull, 277.

**Bradford, E. H. and Lovett, H. W.** Report of progress in orthopedic surgery, 398.

**Breast.** The treatment of fissured nipple, Boardman, W. E., 579.

**Brinton, J. J.** On horny growth of the penis, with exhibition of a remarkable case, 532.

- Bromide of Potassium.** Cutaneous eruptions produced by bromide of potassium, 488.
- Bronchorrhoea** communicating labor, Biles, W. P., 11.
- Brown, W. S.** The rôle of the ovary, 225.
- Bryson, J. H.** On the choice of operation for the removal of vesical calculus in cases complicated by prostatic obstruction, 532.
- Bruce, E. T.** Hergerson's method of treating phthisis, 611.
- Bruce, T. B.** A reducing substance in human urine resembling glucose, 83.
- Brush, E. T.** Mammary glands, 163.
- Bryant, J. D.** Perforation of the appendix vermiformis: laparotomy, 33.
- Buckingham, E. N.** *Tinea saginata* removed by pelletterie, 577.
- Buenos Ayres.** The outbreak of cholera in Buenos Ayres, 122.
- Bulkley, L. D.** Syphilis occurring in connection with other diseases of the skin, 165.
- Bullard, W. N.** Symmetrical atrophy of the lower extremity, with backward dislocation of the tibia, 114; the relations of tea-drinking to disorders of the nervous system, 577.
- Bullock, E. W.** A case of serosal tumor, 189; a case of toxic symptoms arising from the use of cocaine, 575.
- Burns.** Cases of burns with special reference to complications, sequelae and treatment, Cleaves, J. E., 577.
- Burrell, H. L.** Fracture of the spine: its immediate treatment by rectification of the deformity and fixation by plaster-of-Paris jacket, 577.
- Burrell, H. L. and Cushing, H. W.** Report on the progress of surgery, 255, 274.
- Cabot, A. T.** Three cases of stone in the bladder removed by litholaxy, 377; a case of hysterectomy for the relief of pyelitis from obstruction, 517; proctostomy for obstruction, 559.
- Cachexia strumipriva**, 288.
- Caesarian Section.** Successful case of Caesarian section, Lusk, W. T., 483.
- Californine** as a diuretic, Schroeder, W. von, 461.
- California.** The climate of Southern California, Orms, H. S., 610.
- Calomel** as a diuretic, 266.
- Cancer.** A pathognomonic sign of cancer of the stomach, Debove, 98; personal experience in the treatment of cancer, Warren, J. C., 151, 161; cancer of the pancreas, Taylor, J. C., 303.
- Canada.** Improved non-obstructing catheter, Meyer, J. S., 297.
- Carbolic Acid.** Poisoning by carbolic acid, Minot, F., 350.
- Carlsbad.** Carlsbad waters in the treatment of gout and biliousness, Potsdammer, J. B., 113.
- Carpenter, W. M.** The clinical significance of endocardial murmurs, 139.
- Catarrh.** Oil of turpentine in chronic catarthal affections, 143.
- Cell Anthraxosis**, Gregory, E. A., 569.
- Census.** Fourth census of Massachusetts, 289.
- Centenarians.** Collective investigation on centenarians, 41.
- Chadwick, J. R.** Poisonous arsenical wall-papers, 129, 139; a case of hydatiform mole, 293.
- Chancre.** A few statistics on the comparative frequency of the chancre, Greenough, F. R., 531, 545.
- Circulatory System.** Report on progress in thoracic disease, Shattuck, F. C., 295; the use of prophylactic ligatures in heart disease, Bowditch, V. Y., 253, 261; five cases of large visible pulsating artery on the posterior wall of the pharynx, with remarks, Farlow, J. W., 392, 399; a case of embolism of the left vertebral artery, with autopsy, Stuart, F. W., 301, 308; case of aneurism of the innominate, Lyman, G. H., 392, 401; overdistention of the right ventricle, with a report of five cases treated by leeches, Shattuck, F. C., 395, 405; the prognosis in cases of heart disease, Clark, A., 461; an experimental study of the effects of puncture of the heart in cases of chloroform narcosis, Watson, R. A., 325; aneurism of the left subclavian artery for the cure of which three methods of treatment were employed: death, Richardson, T. G., 527; femoral aneurism cured by elevation and flexion of the limb, Richardson, T. G., 528; a case of aneurism of the abdominal aorta, Dana, I. F., 573; causes of cardiac failure in high altitude, Donaldson, F., 579; obstructive safety-valve action in the heart and direct functional murmurs, Gutierrez, J., 581, 626; hemorrhagic infarction, Welch, W. W., 610; clinical aspects of hemorrhagic infarction, Osier, W., 610; notes on a frequent cause of nasal hemorrhage, Robinson, R., 614.
- Channing, W.** Report of a case of epilepsy of forty-five years' duration, with autopsy, 62; recent progress in care of the insane, 351, 352.
- Chapman, S. H.** Myalgia of the pharynx and larynx, 557.
- Charcot.** Abstract of address delivered at the funeral of M. Vulpian, 521.
- Chemistry.** A reducing substance in human urine resembling glucose, Bruce, T. B., 83; reducing substance in the urine, 143; report on medical chemistry, Hills, W. D., 327, 334.
- Children.** The so-called pathological loss in children, Townsend, C. W., 157; report on diseases of children, Rotch, T. M., 471; a contribution to the study of the etiology of the summer diarrhoea of infants, Haven, H. C., 578; cirrhosis of the liver in children, Howard, R. P., 581.
- Chismore, G.** Some cases of pyelitis in which frequent and painful micturition was the chief symptom, 532.
- Chloral hydrate** as a vesicant, 156.
- Chloroform.** A death from chloroform, 269.
- Cholera.** The outbreak of cholera in Buenos Ayres, 122.
- Chorea.** The treatment of chorea, 166.
- Clark, A.** The prognosis in cases of heart disease, 461.
- Clarke, M. D.** House-drainage, 190.
- Cleaves, J. E.** Cases of burns with special reference to complications, sequelae and treatment, 577.
- Climate.** Prophylactic treatment of those who inherit a predisposition to phthisis, Donaldson, F., 569; the philosophy of climatic treatment of diseases of the chest, Leaning, J. H., 761; observations upon the sanitary advantages of Tide Water, Va., including Virginia Beach as a winter health resort, Garnett, A. Y. F., 698; environment in its relation to the progress of bacterial invasion of tuberculosis, Trudeau, L. L., 699; the climate of the sub-peninsula Pinellas, Florida, Van Bibber, W. C., 609; climate of St. Moritz, upper Engadine, Switzerland, Poole, A. C., 619; a classification of American mineral waters, St. Augustine as a health resort, Smith, P. THE INTESTINAL SUTURE.<sup>1</sup>

BY OTIS K. NEWELL, M.D.,  
Assistant in Anatomy at the Harvard Medical School, Boston.

THE subject of intestinal suture is one of such great interest and importance to-day, that I cannot do it full justice in this short paper. But I have endeavored by a brief review of its early history and a more close consideration of its development in the past few years to give a clear idea of the technique of the modern operation.

That this operation also is "no new thing under the sun" is shown by the fact that it was known to Celsus and practiced by many of the surgeons of early times. But notwithstanding that here and there isolated cases were operated upon, and intestinal wounds united by suture in some manner, it was still generally believed, that to meddle in any way with a tender and inflamed intestine, and above all to introduce sutures into it, was a grave and entirely unwarranted procedure. Total division of the intestine was, up to the beginning of the eighteenth century, looked upon as a necessarily fatal condition. Palfin taught, in 1710, that intestinal wounds could not unite, and advocated stitching the bowel to the abdominal wall so as to establish an artificial anus.

But the fact remains that many ingenious and often successful methods were adopted for the closure of intestinal wounds. In the Middle Ages Abulcasem and others made the most daring experiments with this operation. Roger united the intestine over a piece of elder tube, other operators used rolled pasteboard cards, pieces of candle, cork, swine's bladder, dried intestine, and the trachea of an animal.

The latter appears to have been the favorite among the materials thus used, and this method received the name of the Suture of the Four Masters, from its having been used by the four celebrated monks who practiced surgery together at Paris in the middle of the thirteenth century. I may here state that, according to Rydygier, all references to intestinal suture performed in early times, are made in regard to transverse or longitudinal wounds, as the first recorded resection with union of completely divided intestine was the operation done by Duverger in 1837. It is useless to discuss here how the great authorities of different times, and contemporaneous operators, differed in regard to the safety of intestinal suture. Scaupa was opposed to every suture, while Jobert, Reybard, Larrey, Lambert and others were in favor of their use.

In all the early methods, however, the main idea was to approximate the edges of the wound, in a general way, so as to give them an opportunity to heal together, but no definite rules were given for uniting them in any particular manner.

The great epoch in the history of this operation came in 1826, when Lambert, then an interne in one of the Paris hospitals, and a contemporary of Jobert's, who was also an interne, declared that in order to obtain union of sutured intestinal wounds the great essential was to procure careful apposition of the serous coats, and since then this has been the established fact upon which the foundation and success of all following methods have been based. Owing to a

misprint in the first publication of the method Lambert was substituted for Lembert, and hence the frequent misquotations made even at the present time.

But a short time previous to Lambert's discovery, Jobert had published an account of his Invagination Method, and it is not at all unlikely that in the study of it Lambert's idea found its source.

This consisted in invaginating the lower end of the bowel, and then drawing the upper down into it and fastening it in place by means of sutures, two or more in number. These sutures passed through the whole thickness of the bowel and were intended to finally cut their way through and pass off with the stool. This method approximates the serous coats more or less closely and gives quite good chances for union. Its disadvantages, however, are that under ordinary circumstances it is impossible to determine which is the upper end and which the lower end of the bowel. The calibre of the intestine is also too much reduced and the edges of the intestine form a flap which, if the bowels have been inverted in position, will act as a valve giving rise to more or less, often complete and fatal obstruction. It is also necessary to separate the mesentery from the invaginated and inserted portions of the bowels, and this may cause local gangrene from loss of blood-supply.

Reybard's method was particularly adapted to the closure of intestinal wounds with loss of substance. A thin piece of wood was inserted into the intestine, large enough to overlap the edges of the wound. To the centre of this was attached a double thread, each end of which was passed through the abdominal wall at one side of the external opening, and the bowel then drawn firmly against the wall of the abdomen so as to enable it to become attached and thus close the wound.

This method, like that of Palfin and other operators who insisted upon the necessity of fastening the bowel in some manner close to the abdominal parietes, had the advantage of giving the best chance, should union fail to take place, for the formation of an artificial anus, or a localized abscess by means of peritoneal adhesions.

Undoubtedly when union of the intestinal wound did occur after these operations it was because the serous surfaces had been well brought together, but that this was the great essential, none of the operators

FIG. 1.

FIG. 2.

up to the time of Lambert had recognized. He, as already mentioned, was the first to discover the fact since abundantly proved by experiment, that inflamed serous surfaces when in contact tend to unite with great rapidity. A serous and mucous coat will not unite, and mucous surfaces heal together but slowly. Lambert, therefore, made his suture so as to give the best opportunity for this adhesion of serous surfaces. Figs. 1, 2 and 3, in which the suture includes only the serous and muscular coats, illustrate the manner of making this suture.

As readily seen, the edges of the wound are always

<sup>1</sup> Read before the Surgical Section of the Suffolk District Medical Society, May 6th, 1886.

FIG. 3.

nically inverted when the stitches are drawn together. Lembert used the interrupted stitch. Numerous modifications of this suture have since been made, and from among them the operator of to-day must make his choice.

Before considering the modifications of Lembert's suture it will be interesting and possibly of value in connection with emergency cases, to speak of a few methods in which Lembert's principle has been applied without the use of sutures, or with but slight aid from them.

Dedan's ingenious apparatus for uniting completely divided intestine consisted of three rings of silver or tin. Two of these were similar and of a diameter slightly less than that of the intestine. The third was equal in length to both the others but smaller in diameter. The two shorter rings were inserted into the bowel and the ends of the latter invaginated over their inner surface. The third ring was then passed inside of these so that the divided ends met midway upon it. The whole apparatus was held in place by passing a suture threaded at both ends first close to the edge of the rings above and through the inner ring then out again at the edge of the rings below. At each end the needles were now passed in at the point of the former needle puncture, and then up between the outer rings and the bowel to where these rings came together. The needles were finally passed out through the intestine and the suture tied together. The rings were thus held in place and the serous surfaces enabled to unite. After a time the edges of the outer rings cut their way through the portion of bowel included between them, and the apparatus passed off with the stool.

The method of Beranger-Ferand is also very ingenious and was for the union of transverse or longitudinal wounds. Two thin pieces of cork were cut into prismatic shape with a width of about six mm., a thickness of two mm., and a length slightly greater than that of the wound. Small insect-pins were passed through these, their heads being covered in with sealing wax. One of these pieces was introduced into the bowel and the pins passed through the edges of the wound on one side about two or three mm. from its border. The other piece was placed in a similar manner on the opposite side. The edges of the wound were then inverted and the two pieces pressed together. An additional safeguard to their separation may be made at either end by inserting a piece of bent wire, and after the two pieces have been united, pressing this in from the outside. The wound was thus held together and the serous surfaces allowed to unite. The portion of bowel included between the pieces of cork soon ulcerated through and the apparatus passed off with the intestinal contents.

Amussat passed the ends of the divided bowel over a piece of cork deeply grooved in the centre. The ends were made to overlap slightly and the bowel then tied tightly down into the groove with a ligature. This also accomplished the desired result and after a time was discharged from the bowels.

Many other methods of suture, such as those of Gely, Emmert, and other operators are ingenious and interesting, but as they are no longer of much practical value, their description will be here omitted.

Probably the first change in Lembert's style of suture was that made by Czerny, who proposed to unite not only the serous coats but the edges of the wound as well. This he accomplished by using a double row of sutures (Fig. 4). This forms a sort of "Etage Naht" and is certainly, aside from the time it requires, a valuable adjunct, as it serves to protect the Lembert stitches by keeping the intestinal contents away from them. When this suture is made with the Kürschner stitch for the first row it does not require much time.

FIG. 4.

FIG. 5.

Gussenbauer then thought of doing this all with one suture and made his figure-of-eight stitch (Fig. 5). This is an ingenious but complicated suture and has the objection that should the lower portion ulcerate through, the whole stitch would become loosened and thus give rise to the escape of intestinal contents.

The Kürschner suture is a continuous one and (Fig. 6) is made by tying the first stitch and then proceeding as with any continuous suture, puncturing the intestine from within outwards, and fastening the whole, when completed with a seamstress's knot. This is a very rapid and simple suture and closes the wound nicely. Nussbaum prefers it to all others and says, "The simple interrupted suture like Lembert's is very much harder to make, the needle must be laid aside ten or twenty times and the scissors taken in hand, while with the Kürschner suture this need be done but twice."

FIG. 6.

The remaining methods of intestinal suture which I am to describe are of very recent date, and have been used altogether for uniting the ends of resected intestines.

First, we have the method of Neuber used in operating for the cure of artificial anus and made as follows: A circumscribing incision was made through the skin about the anal orifices. The skin was then dissected away from the fascia beneath, and the edges of the flaps thus formed united with a continuous suture so as to prevent the escape of intestinal contents. The ends of the intestine were then loosened and brought down (Fig. 7). The abdominal wound was now closed by provisional sutures, as recommended by Madelung, so that just enough room remained for the ends of the intestine drawn through the wound (Fig. 8). The intestine thus constricted closed the abdominal wound, and prevented the entrance of fecal matter into the field of operation. The bowel was now held by digital compression and after removing a sufficiently large piece of mesentery and tying the bleeding vessels the ends were cut squarely off. (Fig. 8). Neuber now sutured the ends of the bowel together over a piece of decalcified bone tube.

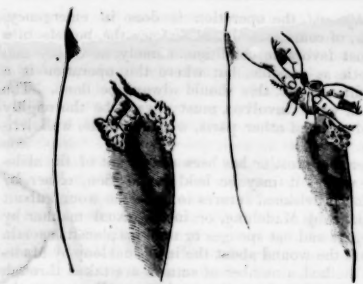

FIG. 7.

FIG. 8.

This tube was about two cm. in diameter, and turned so as to bulge in the central portion and have a deep groove in the middle line (Fig. 9). The sutures were made as follows: First before inserting the tube the ends of the bowel were united by two or three interrupted sutures, taken at the mesenteric insertion. The tube was then inserted and the ends of the bowel drawn closely together over it. The ends were now united by a number of Lembert stitches (Fig. 10 a). The intestine was then drawn down into the groove by means of a constricting "suture" or ligature (Figs. 10 b, and 9), and finally in order to get a most exact union of serous surfaces still another row of interrupted Lembert stitches was taken about one cm. apart (Fig. 10 c, and Fig. 9). Thus finally (Fig. 10 c, and Fig. 9) there was, in the depths of the groove the first row of interrupted sutures, then the constricting "suture" or ligature, and finally an outer row of interrupted sutures.

FIG. 9.

As advantages of this method Neuber claims, first, the ease with which it is performed, it being much easier to sew upon a firm foundation than otherwise. Secondly, the wound of the intestine is protected by the tube from contact with the intestinal contents. Neuber, to obtain the best possible asepsis, powdered a little iodoform into the groove. Thirdly, the tube maintains a free passage for the intestinal contents, which is not always the case with some of the other methods, where at times the collection of fecal matter above the wound owing to more or less stenosis forms a serious and even fatal complication.

FIG. 10.

The intestine has been united in this manner after resection at the Kiel clinic three times, twice by Neuber and once by Schlange, and each time with success. Experiments upon animals have shown that

after from four or five days the decalcified tube disappears. In the cases at the Kiel clinic, careful examinations of the dejections failed to give any trace of the tubes.

Professor Madelung, of Bonn, having in view the fact, well established in experimental pathology by Lister, Maas, Tillmans, Rosenberg, and others, that pieces of living tissue or other substances, when made aseptic, could be placed in the peritoneal cavity, and there become imbedded or encapsuled, and gradually absorbed without causing suppuration, devised what he calls the cartilage-plate suture. This suture is made as follows: The costal cartilage of a young calf is first cut in thin slices, which should have about the thickness, Madelung says, "of sections made by beginners in microscopic work," and the circumference of a small lentil, from four to six millimeters. These slices are prepared in the same manner as antiseptic silk. The ends of the bowel are first united with a Kürschner suture. A No. 12 needle is now threaded so that its eye comes at the middle of the suture. The ends of the suture are then tied together in a double, or better, a treble-knot. The needle is now passed through the centre of one of the cartilage-plates, and the suture drawn through until the knot

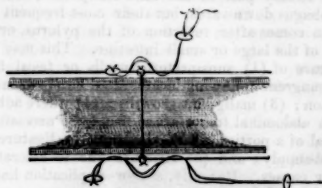

FIG. 11.

comes firmly against the plate. With the suture thus prepared, the needle is passed in the usual manner through the sero-muscular layer of both ends of the bowel, and then through a second cartilage-plate of the same size as the first (Fig. 11). The suture is now cut off close to the needle, and again tied in a treble-knot firmly down to the second plate (Figs. 11 and 12).

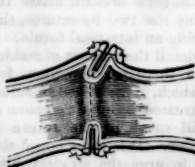

FIG. 12.

FIG. 13.

With the use of this suture, Madelung claims that it is possible, with a much smaller number of stitches, to obtain sufficient contact of the serous surfaces. Circular cutting through of the tissues by the suture is here avoided. If the wound of the serous coat made by the needle is enlarged a little by drawing upon the suture, the cartilage-plate will cover in this opening. Madelung hopes that his suture will not be looked upon as too complicated, and affirms that it is simple and practical in its application.

Mr. Bishop, of Manchester, England, has recently

devised a very ingenious suture, a full and illustrated description of which will be found in last year's January number of "Braithwaite's Retrospect." This suture is unnecessarily complicated, and presents no particular advantages. Besides, being made in a single row, it should not involve the mucous coat, which it does. It has only been used in experimental operations.

So much for the different methods of suturing the intestine. From the first Lambert suture made with the single interrupted stitch, down to the most recent of the after-coming methods, which I believe to be those of Neuber and Madelung, all have been sufficient to secure, with varying frequency of success, union of the ends of a divided intestine, or the edges of transverse and longitudinal intestinal wounds. No method has yet been devised which stands preëminently above all others. That one is the best which secures and maintains the most perfect and undisturbed contact of the serous surfaces with the least reduction of the intestinal calibre, and it will be a matter of personal choice and experience in deciding which one best answers these requirements.

The various forms of intestinal suture may be applied to any part of the alimentary tract from the œsophagus downwards, but their most frequent application comes after resection of the pylorus, or some part of the large or small intestine. This may be for the cure of (1) anus-pretrenaturalis or fœcal fistula; (2) gangrene following incarcerated hernia or intussusception; (3) malignant growths; (4) where adhesions to an abdominal tumor are so firm as to necessitate removal of a portion of the intestine or ligature of its blood-supply; and (5) stricture due to ulceration or other causes. Recently, a new application has been found in Wölfler's operation of gastroenterostomy, a procedure similar to the method illustrated in the "Surgical History of the War of the Rebellion," for uniting two simultaneously-wounded knuckles of intestine, with Gely's suture. Wölfler's operation, suggested to him by Nicoladoni, during a pylorus resection, where, on account of too extensive disease, the pylorus could not be removed, consisted in taking the loop of small intestine nearest the stomach, and after making a longitudinal opening in it, and a corresponding one in the stomach, a finger's breadth above the gastro-colic ligament, uniting the two by sutures, this being done instead of forming an intestinal fistula.

Let us now consider in detail the manner of making the intestinal suture. As there are now very few cases of intestinal lesion, which, if they lead to suture at all, would not be best treated by total resection of the affected portion, I will speak of the suture as applied in the latter operation. It is to be hoped that it is no longer necessary to urge the strictest adherence to the rules of antiseptic surgery, and also that any surgeon who will take upon himself the responsibility of such an operation, should it come as a case of emergency, has always in readiness all of the necessary materials, such as antiseptic sponge material, silk, catgut, needles, etc. It is also necessary to have practised the operation a number of times on post-mortem material, or in experimental operations. The operation should never be hurried; within reasonable limits, the amount of time taken, one hour to one and one-half hours is of no great importance. As far as the success of the operation as such is concerned, the greatest danger lies in failure to apply the stitches

perfectly. If the operation is done in emergency, there is, of course, no chance to get the bowels into the most favorable condition, namely, as empty and antiseptic as possible, but where the operation is a premeditated one, this should always be done. The stomach, when involved, must always be thoroughly washed out, and other parts, when possible, well irrigated.

After the intestine has been drawn out of the abdominal wound it may be held in position, either by applying provisional sutures to close the wound about it, as done by Madelung, or in the usual manner by the fingers and flat sponges or napkins placed beneath. To close the wound about the intestinal loop by Madelung's method, a number of sutures are taken through the abdominal parietes just as they usually are at the end of an operation, and after drawing the wound together tied in a beau-knot so as to be loosed at the end of the operation, when the bowel is to be replaced. They are then used with the additional necessary ones to close the abdominal wound. This method has also been used by Veit, of Bonn, in ovariectomies to prevent the protrusion of intestines while tying the vessels in the pedicle.

Now, when the intestinal loop is fixed, the bowel

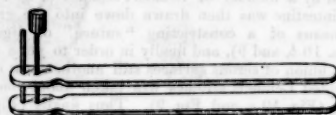

FIG. 14.

must be compressed above and below the portion to be resected, so as to prevent the escape of intestinal contents into the field of operation or the abdominal cavity. This may be done by (1) digital compression, (2) long-bladed forceps with or without covering, (3) provisional ligature with stout catgut or silk, (4) various clamps devised for this purpose.

Rydygier's clamp consists of two flat pieces of iron notched at the ends and enclosed in rubber-tubing. They are fastened with rubber-bands. Makins' clamp is a large bull-dog forceps with a screw closure, the blades to be covered with rubber-tube. I have had made a clamp similar to the Dupuytren-Blasius, one for the cure of artificial anus (Fig. 14.) Its advantages are supposed to be, that the blades, which are also to be covered with rubber-tubing, are kept parallel and the pressure thus made equable. The screw is so arranged, by being weak and not bringing the blades entirely together, that too great pressure cannot be employed. When polypus forceps or other clamps closing at an angle are used, the pressure at the inner part is apt to be too great and give rise to sloughing.

Digital compression is very good but in a long operation the fingers are apt to become very tired, and are, above all, much in the way.

A provisional ligature passed through the mesentery and around the bowel closes the canal very thoroughly but if tied too tightly will give rise to gangrene. It also wrinkles the bowels more or less, which may at times be an inconvenience.

After having closed the bowel in some manner the next step is either to resect the desired amount of intestine with its triangular piece of mesentery and then tie the vessels, or tie the vessels first and then remove

the intestine and mesentery. It seems to me it is much better to first tie the vessels and then remove the bowel with its mesentery. The vessels going to the bowel can be plainly seen or felt and the elimination of the blood-supply made with such exactness that very little if any bleeding will occur after the intestine is divided. The field of operation is thus kept much cleaner. The only objection to this method is that it is said to require more time, but the difference, if any, is very slight and not important.

One important point must now be remembered, and that is, to resect, no matter how much this may increase the difficulty or length of the operation, all intestine which has had its blood-supply removed. This, as already stated, is always easily determined. Operations which might otherwise have been brilliant in their results, have ended fatally through neglect of this point, the post-mortem examinations having shown that gangrene of intestine thus deprived of its blood-supply always occurred.

After the bowel has been resected any contents which may escape from the portions beyond the clamp, must be carefully wiped away and the ends thoroughly cleansed before commencing the suture. At this point, if no clamps have been used it can be seen how difficult it is to distinguish the upper from the lower end of the bowel, for if both contain ingesta they will escape in about equal amount from either opening. The character of the escaping contents is an indication as to what part of the intestinal tract has been opened.

The intestines are now to be united according to the suture employed. The edges of the protruding mucous membrane may now be trimmed off, but this I think inadvisable and of no particular benefit. What seems to me to be the best of the simple sutures is, practically Czerny's, but differs from it in having the first row made with a continuous suture. The first row may be made with the Kürschner suture. For the outer row I used in an experimental operation a suture, which I do not find described, but which may be called a continuous Lembert suture. This was what I understood to be Kürschner's suture, but that suture as described and figured by Nussbaum perforates all the coats from within outwards. The continuous Lembert suture is simple and a great saver of time. It is merely the Lembert stitch made with a continued instead of interrupted suture.

If the material for Neuber's or Madelung's suture is in readiness they too might be used, and from the success which has thus far followed them, no failure of union having occurred, they are probably as certain, if not more so, than any of the others.

Bishop claims as advantages of his suture the fact that the knots are all made on the inside, and after ulcerating through, the stitches pass off with the stool. But the desired object to-day is to have the stitches become encapsuled or absorbed and not cut their way into the bowel. This should be the case with one row at least.

In making the suture it is always best to begin at the mesenteric insertion. This is the most difficult part to unite as the peritoneum over the mesentery is apt to tear away. If this occurs stitches may be later taken, outside of those that tear away. It is much better to hold the folded intestine gently between the fingers and sew with a straight needle and without forceps or needle-holder (Fig. 15). The intestine is

thus injured as little as possible and the suture, by avoiding the constant change from forceps to needle-holder, and *vice versa*, made more rapidly. In pylorus and other operations involving thicker parts, forceps and needle-holder should be used. The needle should be introduced so as to leave, in making a single row suture, two or three mm. of intestine beyond the needle puncture nearest the wound border (Figs. 1, 2, 3). Three or four mm. should be lifted upon the needle each time in sewing (Figs. 3, 4, and 5), and from the thickness of this portion which can be well judged it can be seen how much of the intestinal wall is being included in the stitch. The suture is now continued around the bowel. The stitches should be taken very close together, two or three mm. apart, as what may appear to be close stitches in the contracted bowel, will, when there is distention, as with flatus, be perhaps quite far apart. When this suture is ended it should be thoroughly inspected, and any point where good apposition is doubtful or where the suture has torn away at all, reinforced with one or more extra single stitches. The edges of the mesentery should then be united with a few interrupted sutures. After removal of all clamps and other accessories to the operation which may have been placed about the bowel or elsewhere, the intestine is carefully cleansed and dropped back into place. The abdominal wound is then untied in the usual manner.

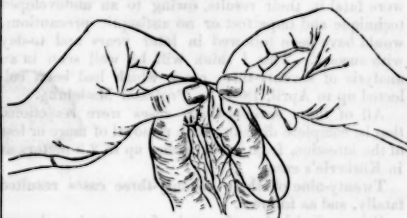

FIG. 15.

The needles used should always be plain, straight, round sewing needles and of the smallest size. A No. 12 English Pearl sewing needle is what is generally used, threaded with the finest conjunctival silk or Japanese silk twist. A No. 10 or 11 needle seems to me to be sufficiently small and is somewhat more convenient to use on account of its length. The finest catgut may also be used, but it is less pliable and above all requires a much larger needle and therefore necessitates a larger puncture wound. The suture may be threaded while dry, and then disinfected. This is done by tying the ends of the threads together and holding the needles in forceps or otherwise and then boiling them one hour in five per cent. carbolic acid solution. (Czerny's method). If it is desired to keep them in readiness they may be placed in alcohol where the needles will not rust. Rydygier in a large number of experimental operations always used catgut and never failed to get good results in cases of simple resection. But aside from the objections already made to catgut is the additional one that should suppuration occur about the wound, or pressure come from fecal masses moving down from above the wound, the silk would be there to resist their tendency to separate the freshly united surfaces, long after the catgut had disappeared. The antiseptic silk becomes readily encapsuled and may

be sewed or tied in anywhere. In order to become encapsuled it must of course remain antiseptic, and since stitches which perforate the mucous membrane must absorb more or less of the intestinal contents they should, it seems to me, never be taken unless it is desired to have them cut their way into the bowel. In addition to this, such stitches make a puncture wound through the wall of the bowel from which fluid contents may escape into the peritoneal cavity.

I have already stated that any disease or injury of the bowel, excepting slight wounds, where intestinal suture is needed, would probably be best treated by total resection of the affected portion and union of the divided ends. This I hold to be so from the fact that other operations necessarily lead to a large degree of stenosis at the point of suture, while in uniting the ends of a resected bowel, the largest possible calibre is obtained. This may be still increased by adopting a method advocated by Madelung and Weber of dividing the ends of the bowel obliquely so as to increase the room for passage at the point of union.

From the nature of the intestinal blood-supply, the edges of the bowel after resection are sure to have an abundant source of nourishment and therefore when properly sutured to unite with certainty.

Finally, let us consider briefly the value of this operation. Statistics are of but little weight in this connection as many of the early operations which were fatal in their results, owing to an undeveloped technique and imperfect or no antiseptic precautions, would have been followed in later years and to-day with success. This I think will be well seen in an analysis of seventy-three cases which had been collected up to April, 1881, by Professor Madelung.

All of these seventy-three cases were resections, that is, complete division, with removal of more or less of the intestine, from a few inches up to 2.5 meters as in Körberle's case.

Twenty-nine of these seventy-three cases resulted fatally, and as follows:

Fifteen died before the end of twenty-four hours, and one other case was probably as rapidly fatal, but owing to incomplete report this is not certain.

One death occurred on the operating table from the entrance of vomitus into the trachea.

Death never followed after the thirteenth day.

Death was due in one case to embolism of the pulmonary artery from an old venous thrombus of the thigh, and occurred four days after the operation.

One patient died from delirium potatorum, and an insane patient from oedema of the brain.

Twice death was due to other simultaneously received wounds.

In six cases peritonitis had already begun at the time of the operation, and was the cause of death.

Three deaths are referred to "wound shock" and inanition marasmus.

One death was caused by stenosis of the intestine, due to a pseudo-ligament below the point of suture.

Five times fatal peritonitis and acute sepsis developed immediately after the operation. In three of these cases fecal matter escaped into the abdomen during the operation.

In seven cases death occurred during the period of convalescence, peritonitis following the escape of fecal matter through the resection wound. Twice this escape of fecal matter was due to incomplete resection of the gangrenous portion of the bowel, and in the

other five to failure to completely close the wound with the suture.

Of these seventy-three recorded operations, fifty-two, with thirty good results, were performed in the years from 1877 to 1881, and the successful operations in this period are, without exception, those of German, Swiss, and Austrian surgeons; and Madelung says: "We have a right to be proud of the blossom to which this branch of operative surgery has come in our day, but we must, nevertheless, understand that only the first step has been made on the new way."

There is no longer any doubt as to the safety of opening the peritoneal cavity, granting, of course, that it is done in the proper manner. The peritoneum, far from being a membrane of the most vulnerable sort, as it was formerly regarded, bears with the greatest tolerance an astonishing amount of cutting, burning, tearing, and manipulation. From the time when the surgery of the serous cavities was limited to a timid approach to the opening of some of the smaller joints, it went on to the free drainage of the chest for the cure of empyema; and so it will be, if it is not already, with the surgery of the abdominal cavity.

Numerous cases of peritonitis, where the parts have been found "glued together and bathed in pus," have been treated by abdominal incision and thorough washing out of the abdominal cavity with large quantities of water, and have made good recoveries. At our last meeting, Dr. John Homans reported a similar case.

To two influences, however, the peritoneum is greatly susceptible, and they are septic absorption and loss of heat. Unlike the skin, naturally adapted to protection from rapid loss of heat, the peritoneum is a moist, evaporating surface, from which, when exposed to the air, the loss of heat is constant and rapid. Wegner, in his valuable investigations and experiments, found, in a medium-sized woman, the area of the skin-surface to be 17,502 sq. cm., while that of the peritoneum was 17,182.

By exposing the peritoneum to rapid loss of heat, a reflex paralytic influence is exerted upon the heart, and unless warmth be rapidly applied, death occurs from collapse.

If an ice-compress is laid upon the exposed intestines of a dog, the heart instantly ceases to beat, while, as Wegner found, a stream of warm vapor may be directed upon them for seven or eight hours without injurious effect.

Wegner further found that animals into whose peritoneal cavity he had injected large quantities of salt solution at the body temperature were never injured by the procedure, but moved about in as lively a manner as ever.

The capacity of the peritoneum for absorption, and, therefore, for infection, is indicated by the fact that in one hour, fluid equal in quantity to eight per cent. of the body weight may be taken up from its cavity, and in two days an amount equal to that of the entire weight of the body. A quantity of chloral solution injected into the peritoneal cavity exerts an almost instantaneous soporific effect. The large peritoneal area and the peristaltic movements are also elements aiding the rapidity of absorption.

These facts present their own argument, and are clear indications of what it is necessary to avoid in peritoneal operations.

Let us, then, hope that when occasion arises for the application of intestinal suture, no traditions in regard

to the dangers which it involves will prevent its being used according to the means of to-day, and many lives thus saved or made comfortable. Without exception, when done with no technical failure, the operation has, in the last few years, been successful, and where death has occurred, it has been not because the intestinal suture failed to accomplish its object, but owing to other conditions involved in the nature of the case.

In conclusion, let me say that to the consultation of various works, mostly recent German ones, I am indebted for the majority of ideas and figures presented in this paper.

### EXCISION OF ELBOW: LOCAL ANÆSTHESIA BY COCAINE.

BY H. W. CUSHING, M.D.

In the case to be reported, the Corning method for producing local anesthesia by cocaine was employed for the purpose of ascertaining its adaptability to major operations.

The method consists in confining a cocaine solution injected subcutaneously in the field of operation by obstructing the circulation, and thus prolonging the anæsthetic effect at will.

The apparatus required is an Esmarch bandage, a flat-band tourniquet and clamp, a subcutaneous syringe, with short and long needles, and cocaine solution.

The operator first dilates the veins of the selected region by compressing the main afferent vessels with the tourniquet, and then maps out their position with a crayon pencil.

The tourniquet is now removed, the limb exsanguined by an Esmarch bandage applied in the usual way, from the distal end to a short distance below seat of operation. The cocaine is now injected superficially over the desired area as rapidly as possible, each injection being 2 to 5 m. of solution, and each succeeding puncture being made at the edge of the reddened surface from the preceding one. When the skin is anesthetized, the drug is injected into the deeper tissue in amounts of from 1 to 2 minims, and the solution forced out of the needle as the point descends through the tissues, so as to diminish the pain before it pierces them.

When the injection, which, according to the originator of the method, should not require more than five minutes, is completed, the tourniquet is applied a short distance above the anesthetized zone, the Esmarch bandage removed, and the patient is ready for the surgeon.

If the anesthesia is found incomplete either by exploratory punctures or after the operation has been commenced, supplementary injections are made in the same manner as the original ones.

This method has been used by J. M. Roberts, of New York (October 14-17, 1885 — *New York Medical Record*, October 24, 1885), to excise the elbow and hip, and for a femoral supra-condyloid osteotomy. By J. R. Conway with the Esmarch bandage, to examine fractures and dislocations. By C. E. Bruce (*Medical Record*, October 24, 1885) for circumcision; and by Wright to remove tumors. Their reported results are extremely favorable. With the exception of the above, I have seen no other record of these uses for cocaine.<sup>1</sup>

My patient was a fairly well-developed, anæmic woman, aged twenty-six, extremely nervous and timid, with chronic arthritis of the left elbow. After being blindfolded, the arm was prepared in the manner just described, and the skin injected with a one per cent. cocaine solution, temperature 100° F., (over an area of which the olecranon was the centre four and a half inches long and from two and a half to three inches in width) at thirty-five separate points. This required nineteen minutes, and 74-100 grains was used, after which the surface appeared as if it had been exposed to a vigorous swarm of hungry mosquitoes. The patient complained of considerable pain from the tourniquet. Pain from the subcutaneous punctures ceased eleven minutes after the first injection.

The anæsthetic area from each puncture varied from one-half to one inch in diameter. The whole area was approximately four inches in length, and from two and one-half to three inches in width. Ten deep injections were now made; amount, 20 m. = 1.5 grain. Pain was felt below a depth of one-quarter to one-half an inch from surface of skin.

The tourniquet was then applied 4 to 5 cm. above upper border of the anæsthetic area thirty minutes after the first injection, and the operation begun. The primary incision, 10 cm. in length, which divided the tissues to the bone, caused no pain, but the attempt to elevate the periosteum from the edges of the wound made the patient wince and cry out.

Nine subperiosteal injections were now made of a four per cent. solution = 17 m. = .68 grains, requiring five minutes. This rendered it possible to continue the operation till the condyles were reached. Then the complaints of pain were renewed, and as I did not care to exceed the amount of cocaine already injected = 1.62 grains, the attempt was abandoned and the operation completed under ether. It would probably have required over two grains, an amount which, in one of Wright's cases, caused such collapse that considerable difficulty was found in resuscitating the patient.

The tourniquet was removed, wound dressed, and the patient sent to the ward. Recovery from the ether occurred without any especial symptoms, except marked nausea and vomiting. At one-and-a-quarter hours after, however, the patient suddenly became unconscious, the pulse weak and rapid, respiration shallow and slow; face pale, pupils dilated; muscles relaxed, except those of inferior maxilla, which were in a state of clonic spasm.

Patient was given a subcutaneous injection of brandy and nitrite of amyl by inhalation. Resuscitation followed without difficulty, improvement of objective symptoms preceding the return of consciousness. The nausea and vomiting disappeared gradually at the end of twenty-four hours, since which time the patient has steadily improved.

The pain following the operation was apparently less than usual, and the local disturbance from the multiple injections apparently did not interfere with the process of repair at the seat of operation.

It is obviously impossible to justly criticise a method from such limited experience as one case furnishes, however carefully observed, but the results obtained seem to indicate that the method has only a limited application and value.

It seems unsafe to use a drug whose internal dose it still undetermined in such amounts as would appar-

<sup>1</sup> Dr. Varick, *New York Medical Journal*, February 20, 1886. Details of amputation of thigh, where ether had caused alarming symptoms; apparently successful.

ently be required to anesthetize areas large enough for capital operations.

It is ineffectual in operations upon osseous structures, since these, as far as I know, are uninfluenced by cocaine in any available means of application. The discomfort of the tourniquet is an important factor, as any one can readily convince himself; and there seems also an uncertainty of affecting the deeper tissues uniformly, although the surface may be perfectly anesthetized.

It increases the time of operating, necessitates additional apparatus, if performed in the manner described by Dr. Corning, and although local pain is absent, an extra strain is imposed on a nervous patient through the mental excitement caused by the strange sights of an operating theatre, and anxiety for one's personal safety, which the unconsciousness from ether prevents. Power of motion also, though at times of great assistance to an operator, will often cause great inconvenience if governed by a patient's volition.

It is, however, of value as a substitute when ether is for any reason contra-indicated, or for operations involving soft parts in limited areas so situated that strangulation of the venous circulation is possible.

The following is a summary of the injections, showing the strength of the solution and the amounts used:

1% solution.	36 injections.	19 minutes.	74-100 gr.	.74
1% "	10 " (deep)	11 "	20 m.	.20
4% "	9 " sub-periost.	5 "	17 m.	.58
	54	36		1.62

In conclusion, I wish to acknowledge my indebtedness to Dr. H. L. Burrell for the opportunity of testing this method.

#### A CASE OF PUERPERAL SEPTICÆMIA, FOLLOWED BY HÆMORRHAGIC CASTS OF THE UTERUS.<sup>1</sup>

BY EDWARD J. FORSTER, M.D.

MRS. A., American, has been three times pregnant. The first pregnancy terminated at the third month. The second at term, the only complication being a slight tear of the perineum for which two stitches were taken; these, unfortunately, sloughed out. Lactation was followed by symptoms of nervous exhaustion, which not yielding to iron and tonics, an examination was made, and, besides the laceration of the perineum, one of the cervix found, the edges rolling out, with the usual accompanying endometritis. An operation was advised and agreed to, but before it could be done, she found herself for the third time pregnant. This pregnancy terminated at term, a male child, nine and a half pounds, O. L. A., cord once around body, large amount liquid amnii.

The nurse, who had been with patient in previous confinement, was directed to wash the external genitals with phenyle solution, and to give daily a vaginal douche of the same. The temperature and pulse remained normal until the sixth day, when a chill occurred, followed by temperature 105°, falling one degree after a vaginal douche of phenyle solution. On the seventh day, the morning temperature was 103°; tenderness over uterus; an interuterine injection was given, and again on the eighth day. A vaginal examination on the tenth day showed a membrane on the sides of the lacerated cervix and on posterior wall of the vagina. After thoroughly wiping off the membrane, a douche of corrosive sublimate, 1 to

2000, was given, and the parts dusted with iodoform. The parts were douched again towards evening, and sulphate of iron and glycerine applied to the cervix. The next morning the temperature was 101°. This treatment with poultices to abdomen was continued until fifteenth day, when the temperature was slightly above 99°. The vagina was daily douched with 1 to 2000 corrosive sublimate solution. Food concentrated or predigested. Champagne, etc., were given.

Owing to my temporary illness, Dr. B. saw the case for the next three days, and found at his first morning visit a temperature of 103½°, the same at night, reaching 104° the two evenings following. At his suggestion and with my concurrence, Dr. W. L. Richardson was called in consultation, who advised the use of uterine iodoform suppositories. About five grains were so given, and this treatment I continued for three days.

Dr. D. took charge of the patient for the next five days, during which time the temperature fluctuated from 99° to 102°. The vaginal douche was continued, the membrane wiped off, and iodoform applied daily. On the twenty-eighth day, the temperature was 100°, and gradually rose to 104° on the thirty-first. During the night the patient vomited, and had a very slight show of blood. At my morning visit, the temperature had dropped to 99½°, and I was told by the nurse that probably the douche might be omitted, as the monthly period had arrived.

Examination showed this not to be the case, but a small clot was removed from the os. On the thirty-fourth day, a clot was removed from the uterus by slight pressure with the end of the speculum. It was about six inches long, and a perfect mould of the uterine cavity. Similar clots were removed from the vagina on the thirty-sixth and thirty-seventh days, and again on the thirty-eighth, but the clot was much smaller; this was the last.

The next day the cervix, for the first time, was found entirely free from membrane. The douching was now discontinued. On the forty-fifth day, induration was plainly felt at the right side of the uterus, the mass appeared about the size of an orange. I supposed we should have a pelvic abscess to treat, but the continued use of the hot douche twice daily caused the tumor to disappear, and finally, on the fifty-sixth day after delivery, the fiftieth after the chill, the temperature was normal.

Iron, strychnia, quinia, and digitalis were given at different times and in different doses during the progress of the case. Ergot was given when the clots first appeared. Hot fomentations or poultices were almost continuously applied to the abdomen, and gave much relief. I have purposely omitted many of the details.

The principal points of interest seem to me to be: The persistency with which membrane, or something which I mistook for such, reappeared, the last seen being thirty-five days after it was first noticed. The formation and passage of the clots at a time when it seemed that they could not be attributed either to the recent confinement or to menstruation.

I think that the cause of the septic poisoning was due to the neglect of the nurse to properly wash the genitals or to give any vaginal douche, as ordered. After the chill, the nurse was alarmed, and gave a douche; this I learned late in the case. An examination of the drains, etc., showed no source of contagion.

<sup>1</sup> Read before the Obstetrical Society of Boston, November 13, 1886.

### Clinical Memoranda.

#### CAUTERIZATION BY NITRATE OF SILVER, TO RELIEVE PERSISTENT RETENTION OF URINE, DUE TO ENLARGED PROSTATE.

BY DAVID G. HALL, M.D.,

Second Assistant Physician to the Northampton Lunatic Hospital.

So little attention has been given to operations upon the prostate gland, that it has become the almost universal custom for surgeons, in cases of retention of urine, due to enlargement of the third lobe of that organ, to employ only palliative measures, and dismiss the case without affording any permanent relief.

In this way, it seems to me, many lives are sacrificed which might be saved or at least prolonged, by the employment of some mild, and at the same time, radical mode of treatment.

Mr. F. Swinford Edwards, in his excellent article on Prostatectomy,<sup>1</sup> refers to "three operations" which may be employed "to relieve retention of urine, from obstruction at the neck of the bladder, whether prostatic or valvular."

1. Excision through a perineal incision.
2. Thermo-electric prostatotomy.
3. Mercier's operation or prostatectomy.

Not daring to attempt any one of these, and yet firm in the belief that the same object could be accomplished by less severe measures; I determined to try, in the following case, the repeated application of nitrate of silver, which, so far as I have been able to ascertain, has never before been employed for this purpose, and I was not a little surprised to receive such gratifying results.

J. W., farmer, native of Germany, was admitted to the Northampton Lunatic Hospital in April, 1880, suffering from chronic mania. The records show nothing of especial interest, until September, 1885, when one of his excitements occurred, during which he insisted upon going without food and sleeping on the bare floor.

One morning he was found to have retention of urine, and examination per rectum, showed a marked enlargement of the prostate. The usual course of treatment, to reduce the inflammation, was followed; but almost complete retention continued for nearly five months. He then began to have hysterical attacks, when an enormous amount of pale urine would be secreted, requiring the frequent use of the catheter, and causing him no little inconvenience.

The first of these occurred during the night, and although an attendant was within easy calling distance, he made no attempt to arouse him.

Distension of the bladder and acute nephritis followed. After this condition of things had been twice repeated, it became evident, that unless some more permanent relief could be afforded, his strength would soon become exhausted.

Among some old discarded instruments, which had formerly been used in the hospital, was one for applying astringents to the urethra, in cases of spermatorrhoea. It was about the size of an ordinary silver catheter, with an opening at the end, from which could be protruded, for about three-fourths of an inch, a female blade, and this being attached to a spiral wire, concealed in the male, could easily be rotated throughout the whole, or any part of a circle. On one

side of the extension, or female blade, was a slot about half an inch in length, evidently designed for holding some semi-solid material, to be applied directly to the affected part. Into this I poured a quantity of melted nitrate of silver, and when cold shaved it down to the size required, that it might be concealed during introduction. The instrument was passed into the bladder when it contained a considerable quantity of urine and withdrawn a short distance. To have the bladder partially filled was thought to be a necessary precaution, to lessen the liability of injury to the parts, in case any portion of the caustic should become detached. The caustic was then exposed by pushing on the ring. After allowing it to remain on the surface of the prostate a few seconds, it was rotated several times, then concealed in the male blade, and the instrument removed. A hard-rubber catheter, well warmed, was fastened in the bladder for a few hours. The cauterization caused but very little pain, and the slight tenderness about the perineum, lasted only a few days. The urine was drawn with a soft-rubber catheter as often as required, and the bladder washed, morning and night, with a three per cent. solution of glycerine and warm water. After five days the operation was repeated.

This time I neglected to fasten a catheter in the bladder, and although less than an hour elapsed before an attempt was made to remove the urine, the instrument was passed with considerable difficulty. Two more operations, making four in all, were performed at intervals of about five days, each one being followed by a marked increase in the size of the stream of urine. It was then found that micturition could be freely accomplished, and there being only a residuum of about an ounce and a half of urine, further interference was considered unnecessary. Six months have now elapsed, and there have been no troublesome symptoms whatever. The bladder has been frequently emptied and washed with a three per cent. solution of glycerine and warm water.

#### A CURIOUS CAUSE OF DEAFNESS.

BY DAVID COGIN, M.D., SALEM, MASS.

DECEMBER 31st, 1885, Mr. X., a slightly-built, American, of about thirty-five years, came to the narrator with the following story: Three weeks before, he received a fist-blow on his neck, beneath the right ear, which rendered him insensible. His adversary was an unusually large and muscular man.

On recovering consciousness, he found he could not hear with his left ear. There had been great impairment in the hearing of the right ear, with an occasional discharge, for several years. He stoutly affirmed that he had always heard well with the left ear, previous to the alteration in which he was assaulted. The right drum membrane presented a small perforation in the inferior, posterior quadrant. No secretion. Watch heard at ten centimetres. The left drum seemed to be quite normal. Tube pervious. Tuning-fork heard in right ear only.

As malingering is always to be looked for in such cases, the writer's "stethoscope-test" for simulated one-sided deafness, was employed, but it only confirmed the patient's statement, that he was absolutely deaf in the left ear.

<sup>1</sup> Lancet, July 11, 1885, p. 87.

Neither vertigo nor pain had at any time been complained of.

Eight months later there had not been any change, save that the hearing was less acute in the right ear, owing to a recent catarrh.

Now, if, as seems probable, the hearing was good in the left ear prior to the blow, what caused its complete abolition?

Is not this a reasonable hypothesis, the *contre-coup* may have caused a total rupture of the *portio mollis*, thus producing deafness, while the firmer *portio dura* was not injured, of which, indeed, there had not been any symptoms.

The writer regrets that he has not been able to try the effects of a blow on a cadaver, which might have helped to settle this somewhat important question.

### Reports of Societies.

#### SUFFOLK DISTRICT MEDICAL SOCIETY. SURGICAL SECTION.

S. J. MIXTER, M.D., SECRETARY.

MAY 5, 1886. DR. GEORGE W. GAY presiding.

DR. O. K. NEWELL read a paper on

#### INTESTINAL SUTURE.<sup>1</sup>

In reply to Dr. Chadwick, the reader said that the stitches should be two to three mm. apart.

DR. CHADWICK spoke of the difficulty that he had experienced in introducing the sutures properly in the living subject, as it is difficult to be sure that the needle is through only the serous and muscular coat. The intestine is also very slippery, and the coats slide upon each other, still further increasing the difficulty of manipulation.

DR. GAY also spoke of the difficulty arising from thinning and stretching the bowel, owing to paralysis of its muscular coat.

DR. MIXTER spoke of the anatomy of the blood-supply of the intestine, and referred to observations of German surgeons, showing that if the intestine is separated from the mesentery for too great an extent, sloughing occurs. Hence, as much intestine should be excised as corresponds to the mesentery detached. Dr. Mixter also referred to the value of one or two provisional sutures in the abdominal wound, so placed that the intestine being operated upon is shut off from the abdominal cavity.

In answer to Dr. Gay, DR. NEWELL said that there was no reason for interrupting the continuous suture at two or more points, as it is not shown that it causes any stricture of the bowel. Dr. Newell showed pieces of human intestine, illustrating the methods of applying the various forms of suture, and also a dog, just killed, whose intestine had been resected and sutured in two places two months previously. The union in both places was perfect.

DR. H. W. CUSHING showed several animals on which various forms of intestinal suture had been performed, and gave a report of his results.

#### EXCISION OF THE ELBOW FOR INJURY.

DR. JOHN HOMANS showed a patient whose elbow-joint he had excised nearly three years before without

removing the condyles of the humerus. The operation was performed at the Massachusetts General Hospital, July 5, 1883. The patient, a railroad laborer, aged twenty-seven, had been struck by a train of cars, and had received a compound fracture of the left elbow, with extensive comminution of the radius and ulna, and severe crushing of the soft parts in the neighborhood. Two and a half inches of the radius and ulna were removed, and the rough ends of the fractured bones sawn off smoothly. All the periosteum was carefully preserved. The operation was performed under the carbolic spray, with all antiseptic precautions. The patient was discharged from the hospital October 13th, having at that time very good motion, but not much power to use the arm. Early in the following April, he resumed his work in a mill, where he was obliged to carry heavy bundles of wool, and he soon found that he could use his left arm about as well as he ever could, and for the same purposes, except that he could not put up a heavy weight. He has constantly gained strength, and now has a perfectly useful arm.

DR. H. W. CUSHING reported a case of

#### EXCISION OF ELBOW: LOCAL ANÆSTHESIA BY COCAINE.<sup>2</sup>

DR. J. W. ELLIOT showed a pair of ovaries that he had removed by laparotomy, together with the tubes. Before the operation the ovaries had been found much enlarged, prolapsed, and very tender. The patient had suffered from neurasthenia for several years, and had been under the treatment of Dr. James J. Putnam for more than a year. The operation was done as a last resort by the advice of Drs. Putnam and John Homans. The patient made a good recovery.

DR. JOHN W. PERKINS showed a specimen of

#### ANGULAR CURVATURE OF THE SPINE.

The specimen was from a woman about fifty years old, with no history. The diseased vertebra, seven in number, occupied the upper dorsal region. The spines were distinct, the bodies coalesced into one piece, with no trace of inter-vertebral substance left. This piece was about twice the height of the adjacent bodies, and bent so as to form an angle of fifty-four (54°) degrees, about which the cord passed. At this point there was an increase in the peridural fat tissue, especially marked on the outside of the canal, where it formed a thick pad opposite the apex of the body, which projected into the canal. The cord itself showed no pathological changes, nor did the vertebrae, other than those above mentioned, there being no thickening, and no signs of any inflammatory deposit, recent or old.

DR. EDWARD T. WILLIAMS exhibited

#### AN APPARATUS FOR THE TREATMENT OF FRACTURED CLAVICLE.

DR. WILLIAMS said that the chief defect with most forms of clavicle apparatus was that the humerus was not properly fixed. It is not enough, as the books teach, to carry the shoulder *upwards, outwards, and backwards*, for unless the humerus is also immovably secured, a constant motion of the fragments takes place, with resulting deformity and shortening. The apparatus exhibited was simply a new form of bandage for fixing the humerus.

<sup>1</sup> See page 1 of the Journal.

<sup>2</sup> See page 7 of the Journal.

Take a piece of sticking-plaster long enough to go nearly, if not quite, round the chest, and wide enough to reach from the axilla nearly to the elbow. Lay it upon the table, spread-side down, and on it place a piece of cotton or linen cloth cut to the same dimensions. Stitch them together across the middle by two parallel seams, from two to three inches apart. Then tear the cloth in strips, lengthwise, after the fashion of a many-tailed bandage. You have then a broad belt of adhesive plaster, secured back to back to a many-tailed bandage.

The plaster-belt goes round the chest, the tailed bandage is to secure the arm. Adjust the belt in position, taking care to have the space between the seams exactly in the mid-axillary line. Then raise the shoulder and pad the axilla in the usual manner, securing the pad by a figure-of-eight bandage or plaster-strip crossed over the sound shoulder, and down into the sound axilla. Then bring the tails of the bandage around the humerus and pin them, supporting the forearm, as usual, in a sling. The interval between the two seams of the bandage is to give space for the brachial vessels, and to avoid undue constriction of the arm.

#### PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

CHARLES M. GREEN, M.D., SECRETARY.

NOVEMBER 14, 1886, the President, DR. A. D. SINCLAIR, in the chair.

DR. SINCLAIR reported the following case of

#### INDUCTION OF PREMATURE LABOR IN A PRIMIPARA, BY MANUAL DILATATION OF THE VAGINA AND CERVIX UTERI.<sup>1</sup>

On the 12th of October last I was asked by Dr. W. L. Richardson, who was sent for but could not attend, to go to a distant part of the country, to see a primipara in the ninth month of pregnancy, who was reported as being the subject of albuminuria, general edema and blindness. Examination of the urine showed, specific gravity 1022, acid, albumen in large amount, blood and granular casts. After a conference with her medical attendant, a personal examination of the patient, and much subsequent discussion of the case, it was decided to resort to premature delivery for the safety of the woman and child. The patient, twenty-nine years of age, became pregnant in January. The progress of gestation was not remarkable until July, when she became generally oedematous. From that time until that of my visit this state of things continued, with persistent albuminuria and casts. The amount of albumen varied under treatment from three to seven per cent. On the 8th of October she became blind. It may have some significance, that on that day the urine contained but about one per cent. of albumen. The amount of urine passed was never scanty. Ophthalmoscopic examination of the eyes reported retinal disorder characteristic of the renal disease. Everything was being done to ameliorate the patient's condition, and to carry her

over to the estimated term of natural delivery; but the blindness, the edema, and the bad state of the kidneys remained. The patient, a refined and educated lady, was aware of the gravity of her condition and correspondingly affected. It was calculated that she might yet have seventeen to twenty days before the natural term of pregnancy would be completed. Would it have been wise to incur the risk of delay in the presence of this alarming state of things?

In view of contingencies, it was decided by the three attending physicians, and concurred in by myself, that delay might at any moment, by further complications, become fatal to mother and child; and in order to avert threatened calamity the patient was etherized and delivered, by manual dilatation of the vagina and cervix uteri, in three-quarters of an hour's time, of a living child, turned and extracted by the feet. Not a fibre of the mother's tissues was torn in the process of delivery. The placenta was taken from the uterus, which contracted firmly. The vagina was douché with a solution of corrosive sublimate (1 to 2000) and the patient made comfortable in bed. In coming out of the ether she was restless and nervous, and her physician, who remained with her during the night, gave a subcutaneous injection of morphia which relieved her. She appeared better before leaving, the morning following.

November 3d. By report: eye-sight returning gradually, no edema, passes sixty to seventy-five ounces urine daily, one per cent. albumen, no casts, no blood, no pus. Took a short carriage drive on the twentieth day after delivery. General health improved; sleeps, eats, and digests well. Child thriving on artificial diet.

DR. B. CUSHING, present by invitation, had seen a similar case thirty years ago, in which there was total blindness; but the woman went to term, and both mother and child did well. He asked the reader if it would not have been better to leave his case to nature.

DR. SINCLAIR thought it would not have seemed so to any one who saw the case.

DR. LYMAN believed in terminating such cases prematurely, and thought statistics demonstrated better results from immediate delivery than from the choice of an expectant method. If the case were left to nature, he would fear disastrous effects on the eye-sight.

DR. RICHARDSON thought it safer to induce labor for the sake of the kidneys. When the kidney symptoms are of sudden onset, even if the urine discloses a grave state of affairs, the kidney will usually clear up after delivery; but when the invasion has been gradual, and marked symptoms have developed, there was great danger of permanent injury to the kidney, if the case were not terminated promptly. He believed that albuminuric retinitis was generally recovered from.

DR. W. P. BOLLES, a guest, reported, by invitation, the following

#### CASE OF BRONCHORRHEA COMPLICATING LABOR.

Mrs. I. P. H., a primipara about twenty-five years of age, engaged me early to attend her. Up to the beginning of the eighth month, she reported herself as perfectly well; she had had but little nausea, did her own work, and was out a good deal besides. Naturally plump and of a phlegmatic temperament, she had grown more fat and heavy since her marriage. Two months or so before delivery, I was called one night

<sup>1</sup> As a contribution to the scanty literature of this subject I have brought forward my last experience on its use. At our last meeting when the subject of manual dilatation was discussed, I said that the subject was still *sub judice*, and that Barnes' bags had still the field. I agree with what was then said by Dr. Green, and think that Barnes' dilators may be combined or alternated with the hand in exceptional cases of hardness of the cervix uteri, the dilatation to be finished by the hand. I pursued this plan once in 1874, using Molesworth's dilators and finishing dilatation with the hand.

to see her, on account of a dizzy or faint spell, from which she had recovered before my arrival; and a few times after this she had several rather slight dizzy attacks: for a week or two she was pale. From these attacks she gradually recovered, and at the time of her confinement she was feeling well and strong.

At the beginning of the attendance above mentioned, a sample of urine of very light color had a specific gravity of just 1000 by my urinometer, which has an error of about four parts at that point, making the true specific gravity, say 1004. Next day it was measured and amounted to three quarts, with a specific weight of 1009 (corrected); no casts or other abnormality save dilution. At further intervals of one or two weeks it was repeatedly examined, always being in the neighborhood of 1010, and measuring about three quarts. So after searching in vain for other symptoms of trouble, the dizzy spells having passed off, I attributed it to simple polydipsia, which was her habit, and gave it no further attention.

The labor presented no peculiarities at its beginning, but was slow in consequence of the size of the child and the fatness of the patient, and was finally terminated by forceps, for which the patient was etherized. She did not take kindly to the ether; complained much of its choking her, and even when half under it in the middle of a hard pain would thrust the sponge away as if the suffocation of the ether was worse than the labor. Suddenly, when fully under its influence, she became livid, the tongue protruded, and respiration ceased: with a little shaking and air she was made to breathe again, and the labor was terminated. She remained however quite blue for several hours, and even on the next day had hardly recovered her color: the respiration, which until then had not been remarkable, after the spell of asphyxia was very hurried and remained as high as forty or fifty per minute for a number of days. The pulse was also much accelerated.

On the second day she had a sharp chill and moderate fever ( $101^{\circ}$  or  $102^{\circ}$ ), and the lower lobe of the left lung (which had not been listened to before) was dull and full of fine mucous râles; respiration not distinctly bronchial, but obscured by the râles. On the third day she was a little better, with about the same physical signs, when I left her in Dr. C. E. Stedman's hands, and she made a quick and complete recovery.

At the time of the asphyxia the mouth and trachea filled with liquid, and the aspect was very much like that of an instance of fatal bronchorrhœa that I once saw in a child as the result of etherization; but the flow continued for only a few minutes before it nearly disappeared, although gurgling and moist respiration were present for hours. The chills and the signs in the left lung on the following day seem to me to indicate a congestion of the lobe affected, brought on by the presence of so unusual an amount of fluid in the bronchi, and happily terminating in quick resolution, instead of solidification.

Dr. CUSHING spoke of a patient who passed through her first and second labor without trouble; but in her third labor the use of ether was followed by bronchorrhœa, and he feared she would die; but she recovered. This was his only experience of the kind.

Dr. LYMAN said that in a case of eclampsia, having given ether without effect, he gave pilocarpine: profuse bronchorrhœa followed, which he had always supposed was due to the pilocarpine; but perhaps it was attributable to the ether.

#### EXAMINATION OF THE URINE DURING PREGNANCY.

Dr. REYNOLDS raised the following questions: Should the urine be examined frequently during pregnancy, when there are no rational symptoms of kidney affection? Is a physician to blame, if he does not? Is he fussy, if he does? His own practice was to make frequent examinations of the urine.

Dr. BOARDMAN said: Suppose the patient is found to be albuminuric, but without renal symptoms, what should be done about it?

Dr. REYNOLDS in reply said that such a patient should be closely watched: she may not probably be eclamptic; but the condition of the bowels, the appetite, and the habits of sleep should be looked after, and the patient brought into good condition.

Dr. FORSTER reported

#### A CASE OF PUERPERAL DYPHThERIA, FOLLOWED BY HÆMORRHAGIC CASTS OF THE UTERUS.<sup>2</sup>

Discussion on this communication was deferred.

#### NEW YORK NEUROLOGICAL SOCIETY.

STATED meeting, December 7, 1886.

C. L. DANA, M.D., President, in the chair.

#### A CASE OF PROGRESSIVE MUSCULAR ATROPHY, WITH BULBAR SYMPTOMS.

Dr. W. R. BIRDSALL presented the patient, and read the history of a case of progressive muscular atrophy with bulbar symptoms, the atrophy limited to the left upper extremity, the abductor indicis of the right hand and the tongue, the latter affected bilaterally, predominantly on the left side. He presented the case as illustrating the non-conformity of disease to our arbitrary standards of classification and description of types of disease.

The patient showed peculiarities due to the pathological process having advanced to an extreme degree in certain regions, while its distribution had remained limited, not involving neighboring parts usually affected, the left upper extremity and tongue being the parts involved, and to a marked degree, while the right upper extremity was normal excepting the abductor indicis; the trunk and lower extremities remained healthy. A detailed history of the case was given, the patient being a carpenter, a Swede, aged thirty-nine, married, of temperate habits, without a history of syphilis or other disease. A chart was presented, showing the electrical reactions.

Dr. E. C. SQUIN had seen very few examples of unilateral progressive muscular atrophy. He had at present one patient under observation in whom the muscular atrophy was limited to one side, presenting the electrical and other characters of progressive muscular atrophy.

Dr. W. M. LESZYNSKY had a girl aged seventeen under observation, in whom the atrophy was unilateral, affecting only the supraspinatus, deltoid, and a portion of the trapezius.

#### SELF-ABUSE IN ITS RELATION TO INSANITY.

Dr. E. C. SPITZKA, the author of the paper, after citing the views of the classical writers, stated that the question of the existence of a special form of insanity

<sup>2</sup> See page 8 of the Journal.

due to self-abuse and to nothing else, was complicated by the existence of another well-demarcated affection known as the insanity of pubescence. The mental diseases due to self-abuse usually occurred at the same period of life as the latter disorder. This fact explained the similarity of many clinical features between them. The question was further complicated by the fact that hebephreniacs sufferers from pubescent insanity are often addicted to self-abuse, and that thus the features of one disorder may be engrafted upon the other.

The continental authorities do not recognize a special form of masturbational insanity in their tables. Schüle, it is true, speaks of *onanistic insanity* in the sense in which Maudsley uses that term, but he assigns no part to it in his classification, and disposes of it in a few lines. Kraft-Ebing recognizes the vice as an etiological factor, and speaks of such and such forms of insanity on a masturbational basis. He, as well as Schüle, with the majority of recent German writers, follows Ellinger in attributing to the *masturbatory neurosis* a relation to the development of insanity analogous to heredity and other admitted predisposing and determining factors.

I have yet to find any dissent expressed by these authorities from the position taken by Emminghaus, who claims that, owing to its causal relationship to widely differing forms of insanity, it is not proper to speak, as Skae does, of a special form due to masturbation. This critical remark would seem to be supported not only by the clinical facts accessible to every observer, but also by the confusion existing among those writers who have attempted to define and demarcate such an affection. Skae speaks of a peculiar imbecility and shy habits as characterizing the disorder among the youthful, and suspicion and fear, and scared looks, palpitation and feeble bodies as found in older victims, who gradually pass into dementia.

The most distinguished follower of Skae attributes the following symptoms to that form of insanity of which masturbation is the chief cause and "the chief symptom present," giving "the whole case distinct features": Exaggerated self-feeling, concealed shallow introspection, frothy emotional religious notions, and a restless, unsettled state, with foolish hatchings of philanthropic schemes. Luther Bell, who, with Isaac Ray, was among the earliest to attribute special symptoms to insanity caused by masturbation, furnishes a very faithful picture of certain cases, whose particular feature he describes as being a tendency to dementia, a loss of self-respect, a sulky, mischievous, and dangerous disposition, and a subjectively irritable and depressed state of mind. Griesinger, who does not recognize a special form, and denies specific characters, admits that the majority of cases are marked by a profound dulness of sentiment and mental exhaustion, by religious delusions and hallucinations of hearing, and a rapid transition to dementia in the event of incurability, which latter is the usual issue.

The effect of masturbation on the mind and nervous system varies according to the age at which it is commenced. Like other agents which are injurious to the developing brain, such as epilepsy, alcohol and syphilis, its effect is most rapid and serious in the young or children, less so in adolescents, and least marked in adults, unless protracted. For very young infants it causes a profound deterioration, manifesting itself in convulsive, choreic disorder, and imbecility. In those who masturbate between the fifth and tenth years, the

effects seem to be manifested chiefly in arrested brain nutrition. Spontaneity of thought and action is absent with such children; they do not play as their comrades do.

There are a number of other circumstances which modify the development of mental disturbance in masturbators. The age between twenty and thirty-five is pre-eminently the period of somatic introspection. It is at this period, if at any, that the average man begins to think about his bodily condition. In these years men weigh themselves, discover that they have too much or too little flesh, develop slight gastric or intestinal disorders, reflex nervous symptoms, or indulge to excess in tobacco, in baccho, and in venere, and consequently are on the *qui vive* for the occurrence of cardiac, renal, or venereal disease, or of sexual disability. It is at this period that the results of masturbation are most deeply felt by a large proportion of the victims of that habit. The prevalent tendency of his age and of his associates of the same age, carries him into a veritable nosomania. Perhaps also, he attempts, under lay or medical advice, to accomplish coitus, and fails. It is for this reason that we find the larger portion of cases of insanity due to masturbation developing between the twenty-fifth and thirty-fifth year, classified as "hypochondriacal paranoia."

A number of typical histories were then related, from which the author drew the following conclusions:

1. Self-abuse is an etiological factor in a large number of cases of insanity, but only those cases should be designated as insanity of masturbation in which the connection between the excesses and the symptoms is direct.
2. Self-abuse, to produce insanity, must have been carried very far, or the subject must be predisposed. Often onanism can be traced in other members of the family, and very often it is found that the maternal ancestry is a weak one.
3. Mania, melancholia, and epilepsy occasionally occur in young masturbators, the former two usually having a favorable prognosis.
4. Stuporous insanity and katatonia are both common, and the former presents good prospects.
5. The forms thus far mentioned when occurring in masturbators present no essential difference from the typical psychoses. They should therefore be designated as mania, melancholia, stupor, etc., from masturbation, and not as masturbational insanity.
6. There is a chronic delusional insanity in grown persons who have been devotees of self-abuse, and it is usually a hypochondriacal *paranoia*. Clinically it is very like typical paranoia, and etiologically it is not the direct result of self-abuse, but rather of an intermediate neurosis. A cerebro-spinal irritation which is due to self-abuse.
7. Finally, there is a form of insanity developing about or after the period of puberty which does merit the name "Masturbational insanity." It is chronic, has a tendency to aggravated dementia, is characterized in its early period by anxiety, timidity, suspicion, fear, and a cowardly, mean disposition. Later there are confusion, meddlesome aggressive behavior, vague delusions, loss of memory, and finally deterioration. After these are observed spells of fury or destructive-ness. This form is never due to any other cause, and resembles no other form of insanity than the one already alluded to.

8. It is not always possible to differentiate between the insanity of pubescence and the form described. But where the former disorder is uncomplicated by the latter, it may be known by a history of peculiarities in infancy and childhood, by the greater constancy of the mental state which in onanists is exceedingly variable. Hebephreniacs are more apt to be expansive in their notions, more inclined to favor projects of a chimerical character. In other words, insanity of pubescence is the paranoia of adolescence, and masturbational insanity the presenile dementia of the same period of life.

DR. RALPH L. PARSONS made some remarks with reference to the treatment. The diet should be principally vegetables and milk, with little meat and stimulating condiments. As the patient sought solitude, he should be thrown as much as possible with others, not alone of his own sex, but also of the opposite sex. He should be kept occupied, and manual labor of some form, like farming, was best. He knew of no special benefit to be derived from medicinal treatment as with the bromides, or with the application of irritating substances to the penis. Cutting off the prepuce might be of advantage in some cases. The patient should be closely watched day and night, mechanical appliances might sometimes be necessary, moral influence could be depended upon to a certain extent.

DR. KELLOGG agreed with the author in the conclusions arrived at in the main. But he should like to know Dr. Spitzka's views as to the relative importance of artificial sexual indulgence and indulgence in the natural manner as factors in the production of insanity. Masturbation was a wide term, and ought to be defined. The effects in some cases were more observable in spinal lesions, in others in cerebral lesions. He believed that masturbation itself was not capable of producing insanity in a person of sound heritage. He was convinced that it was capable of suspending mental growth and producing forms of imbecility in those of sound parentage. He knew it could produce insanity at the time of pubescence, and there were persons of mature age who had a predisposition to insanity in whom the attack was excited directly by sexual excess. Occasionally persons indulged to excess for a year or two only, as did sailors sometimes when on long voyages. Masturbation was also capable of producing insanity in old persons who were on the decline; it hastened dementia. He did not think there was a peculiar set of symptoms; the age of the patient, his education, his heritage, his whole mental make-up influenced the symptoms more than the exciting cause. He did not believe it possible to separate masturbation from other forms of sexual excess, and the title "sexual-abuse" would have been more appropriate because more comprehensive than self-abuse.

DR. NOTES said the case referred to by the author as having been cured, was the only one in the Bloomington Asylum in which a cure had been effected, and he attributed recovery in that case to transferring the patient to a farm, where his whole mode of life, including diet, was changed, and for the better.

DR. L. C. GRAY thought the author had given an accurate description of the mental disturbances often seen associated with the habit of masturbation, but he asked if he did not also find similar mental disturbances in individuals who were not masturbators.

DR. SPITZKA replied that in individual cases he had, but not in groups of cases as occurred in masturbators.

DR. GRAY had seen the mental disturbances described in patients addicted to masturbation, but he had been unable to decide as to what extent masturbation could be considered as a cause or simply an associated habit. He had two cases in mind in which that group of symptoms were followed in the course of a few weeks by masturbation in individuals who had not previously been addicted to self-abuse. He had seen the same symptoms follow excessive sexual intercourse. He had in some cases noticed very exaggerated and extensive cremaster reflex.

In closing the discussion, Dr. Spitzka said that there were undoubtedly some forms of sexual vice which were physically as injurious as onanism, but he had not seen a sufficient number of cases to enable him to say anything about their mental sequelae, unless he cared to risk being premature. He had known epilepsy and stupor to follow natural sexual excess in a young person, and parietic dementia in more than one cunnilinguist and sodomist. The form he had sketched was, as far as his experience went, only found in masturbators. While he admitted with Dr. Kellogg that the single act of onanism was physically not a formal thing, and not much, if anything, different from normal coitus; there were two respects in which the onanist and libertine differed most widely, one was a moral, the other a physical, feature. The onanist practices a secret crime, the social and gregarious element is excluded. Knowing that his act is despised, he becomes inclined to suspicion and fear of discovery. A libertine cannot exceed beyond a certain limit. Coitus requires a certain condition of the organs which implies the existence of certain normal energies. When these fail the limit is set to further excess. With the onanist it is much different. There are masturbators who require no erection; yea, who succeed in their injurious act without any manipulation. The consequence is that they pass far beyond the limit set by nature to natural excess, and no calculation can be made of the damage done.

Dr. Parsons's dietary propositions were endorsed by the highest authority. Individually, the speaker was not decided in his own mind whether a highly nutritious diet would prove injurious in certain phases.

#### TRANSACTIONS OF THE CHICAGO GYNÆCOLOGICAL SOCIETY.

REGULAR Meeting, Friday, November 19th, 1886. The PRESIDENT, CHARLES WARRINGTON EARL, M. D., in the chair.

DR. W. W. JAGGARD read a paper entitled,

A CASE OF CHRONIC INVERSION OF THE UTERUS, OF TWENTY-ONE MONTHS STANDING, REDUCED BY COLPEURYYSIS.

*History.* E. S., thirty-six years old, German; married at the age of twenty-two years; seven children, no miscarriages. Her first six confinements were normal. She was in the habit, common among German peasant women, of rising upon the third day and of making up her own bed. In each of her labors she was attended by a midwife.

Her seventh confinement occurred in October, 1884.

According to the statement of the patient and the attendant midwife, the delivery of the child was normal. The placenta was removed, as in the six former labors, by traction on the cord. During the labor and the *puerperium*, no unusual loss of blood was observed, and the patient does not remember any extraordinary sensations of pain or faintness. The midwife consulted a physician on the second day of the lying-in period, with reference to the sudden development of high bodily temperature. On the same day, a well-known obstetrician saw the case. He made the diagnosis of puerperal fever, instituted the usual plan of treatment, but declined further connection with the case, as he feared the infection of his regular puerperal patients, of whom he had a large number. No examination of the uterus, either by abdominal palpation or vaginal exploration, was made. On the third day an equally competent practitioner inspected the patient, confirmed the diagnosis of puerperal fever, and gave directions with reference to treatment. The contour of the uterus was not investigated either through the abdominal parietes or by the vagina. He continued to visit the patient for eight days, when he pronounced her convalescent.

At the expiration of three weeks the woman rose from her bed for the first time, when she observed a fleshy tumor protruding from the vulva. Seven weeks after delivery she resumed her work as a washer-woman. She suckled her child fourteen months. During this period, painful coitus and the sensation of the presence of a foreign body within the vagina were the only symptoms which attracted her attention to her condition. She noticed no fluor, no hemorrhage, and felt no pain except during coitus. The sexual act was not attended by any perceptible loss of blood. On account of the two symptoms mentioned she sought medical advice. The fleshy mass, situated entirely within the vagina, was supported by a large sponge.

The child was weaned in December, 1885. About March 17th, 1886, she experienced severe metrorrhagia, entirely without pain, and lasting six days. She supposed menstruation had been re-established, and gave the subject no further thought. About April 15th, another severe hemorrhage occurred, painless and lasting one week. On May 28th, she came under the writer's observation, and was admitted into the wards of Mercy Hospital. She sought relief, as she very distinctly expressed it, on account of painful coitus, the sensation of the presence of a foreign body within the vagina, and the excessive loss of blood during her last two menstrual periods. The woman was of medium size and height, with well-developed muscles and clavicles like a man's. She presented evidence of marked anemia.

**Diagnosis.** Bimanual palpation revealed a pyriform tumor, the size of a hen's egg, protruding through the *os uteri*. The base of the tumor rested upon the pelvic floor, and upon coughing or straining appeared at the genital fissure. A shallow sulcus between the pedicle of the tumor and the walls of the cervical canal extending around the left semi-circumference of the canal, could be felt by the finger and traced with the sound. On the right side, no sulcus could be detected, and the membrane covering the tumor was reflected directly upon the external *os*. The long axis of the tumor was deflected to the left of the median line. The *corpus uteri* was absent from the normal position. The tumor, insensitive to pressure,

was covered by a soft, villous membrane, and possessed the consistence of an edematous myoma. The enveloping membrane was of a bluish-red color, presenting some spots of superficial ulceration, and bled upon the slightest touch. Tubal ostia were nowhere visible. Traction of the tumor downwards caused the sulcus on the left side to disappear entirely, an important diagnostic sign of inversion of the uterus, to which Carl Braum, Robert Barnes and Schroeder, in particular, have called attention. Reamy, of Cincinnati, has recently described a sign which might have furnished corroborative evidence at this stage of the diagnosis in the case under consideration. Reamy says that when the tumor, grasped by the fingers within the vagina, can be easily rotated on its vertical axis, it is probably a polyp, since such rotation could not occur to any marked extent in an inverted uterus, stiffened as it is by its muscular walls and the thick, strong, fibrous gray ropes furnished by the broad ligaments.

To make the differential diagnosis between inversion of the uterus and a pedunculated fibroid, positive, the patient was etherized. A sound in the bladder and a finger in the rectum were easily approximated above the tumor. The funnel-shaped cavity at the seat of inversion was easily recognized by the finger in the rectum, and by the hand on the abdomen in bimanual palpation.

No appearances were present that would indicate the invasion of the uterine walls by any new formation.

**Treatment.** The patient was etherized, the contents of the rectum and bladder were evacuated, and the genitalia disinfected. The right hand was passed into the vagina, "and with the fingers and thumb encircling the portion of the body close to the seat of the inversion, the fundus was allowed to rest in the palm of the hand. This portion of the body was firmly grasped and pushed upward, and the fingers were then immediately separated to their utmost; at the same time the other hand was employed over the abdomen in the attempt to roll out the parts forming the ring, by sliding the abdominal parietes over its edge." At the expiration of forty-five minutes, the writer's right hand was almost powerless, and Dr. E. C. Dudley kindly relieved him. Dr. Dudley gave up the attempt at reduction after thirty minutes' trial, fearing perforation of the fundus. Apparently not the slightest progress in the reinversion of the organ had been made. Some hemorrhage occurred as the result of manipulation, although the fundus had been enveloped with absorbent cotton and gauze. The manœuvre was repeated on the following day, under the same conditions, through the same period of time, with no more favorable result.

Emmet's method was then abandoned, for the following reasons. The separation of the fingers to their utmost had no effect whatever in the dilatation of the *os externum*. As pointed out by Fenger, and as brief reflection will convince the most casual observer, mere extension of the fingers can have but little effect in the dilatation of the cervix, owing to the relatively feeble character of the extensor muscles of the forearm. The necessary manipulation of the congested *mucosa*, even when protected by cotton or gauze, caused a loss of blood of moment in an already anemic woman. The uterine musculature had evidently undergone fatty degeneration and there was serious

danger of perforation. Finally, there was reason to entertain fear as to the patient's power to endure the shock from taxis, and the effect of prolonged anaesthesia.

Compression of the body of the uterus opposite to each tubal ostium, between the thumb and forefinger, so as to produce indentation of one side or the other, the Kiwisch-Noeggerath method was equally ineffectual.

On Sunday, May 30th, at the suggestion of Dr. W. H. Byford and Dr. Christian Fenger, the writer began an attempt to effect reinversion by colpeurynter. After the evacuation of the contents of the bladder and rectum, and disinfection of the genital canal, the colpeurynter was introduced while empty, so that it lay on the posterior wall of the vagina and the *fundus uteri* was adjusted so that the long axis of the uterus and the axis of the pelvic inlet were coincident. The bag was then injected with water until it was fully distended. The patient was placed in bed in the dorsal decubitus. The instrument was removed at the expiration of twenty-four hours, and the genital canal disinfected. A suppository containing thirty grains of iodoform was placed in the vaginal *cul de sac*, and the colpeurynter, after being cleansed, was reintroduced. Colpeurynter was continued in the manner indicated without interruption until June 9th. Very gradually the sulcus between the pedicle of the tumor and the neck of the uterus deepened, until on the eleventh day the organ was so far reinverted that the fundus was on the same plane with the *os externum*. During this period gentle efforts at taxis were made daily but without any apparent effect. No perceptible progress was made during the succeeding eight days. June 17th, a serous fluid tinged with blood began to escape from the vagina, and it was thought the patient was about to menstruate. The colpeurynter was accordingly withdrawn. During the nights of June 18th and 21st the patient suffered severe uterine hemorrhages which threatened to prove immediately fatal. Hot vinegar was used as a vaginal douche, but did not prove so efficient a styptic as a hot saturated solution of alum. Menstruation ceased on June 23d. On account of the hemorrhages, it was deemed inexpedient to expose the patient to the fatigue consequent upon any attempt to observe the *mucosa* during menstruation. During the subsequent nine days the writer was indisposed, so that the treatment by colpeurynter was resumed on July 2d. On examination, before replacing the bag, the inversion was found to be as complete and as irreducible as the day on which the treatment began. The uterus was gradually reinverted, as before, until on July 8th, the fundus was on the same plane with the *os externum*. From the 8th until the 15th of July no apparent progress was made in reduction. On the evening of July 16th the writer was very much pleased to find the uterus completely reinverted, and the vaginal portion of the cervix occupying its normal position. The sound passed into the uterus to the extent of three and one-half inches. The *corpus uteri* was felt on bimanual palpation, in a position of slight retroversion, below the promontory of the sacrum. The patient was not aware of any change in her condition. She said, however, that she had felt a sudden, sharp pain in the hypogastric region some four hours prior to the examination. Owing to the patient's enfeebled condition—due in the main part to anemia—she was not permitted to leave her bed until July 18th.

The colpeurynter was in the vagina altogether thirty-three days. On three occasions during this period the bodily temperature rose to 102° F., but invariably fell to the normal after irrigation of the vagina and disinfection of the rubber bag. The presence of the colpeurynter in the vagina did not interfere at all with the functions of urination and defecation. The writer desired to express in words his appreciation of the constant attention devoted to the somewhat tedious plan of treatment, by Dr. Louis E. Lawson, late Resident Physician, Mercy Hospital.

Dr. Alex. J. Stone, of St. Paul, kindly repaired the bilateral laceration of the cervix, on July 20th. The operation was unusually difficult on account of the extent of the tear, and the shortness of the vaginal portion. Dr. Stone's method of operative procedure differs materially from Emmet's, but its description is obviously out of place in the present report. The sutures were removed on August 4th, perfect union having been secured.

The patient, after leaving the hospital, gained rapidly in strength. Menstruation occurred September 26th; the process was painless, lasted four days, and the quantity of blood lost was normal. At the time of writing she had resumed her former occupation.

#### REMARKS.

The case is of particular interest with reference to (1) anatomy, (2) symptoms, and (3) treatment.

(1) *Anatomy.* The uterus was in a state intermediate between the second and third degree of inversion. In the second degree of inversion—the incomplete inversion of Puzos, Levret, Leroux, Donné, the third degree, or perversion of Crosse—the anatomical limit of inversion has been indicated by Baudeloque as the vaginal insertion around the *cervix uteri*. Under these conditions, according to Veit and Freund, the cervical canal is intact, the uterus is only inverted as far as the internal os, and the uterine globe remains within the vagina. In the third degree, the complete inversion of Puzos, Levret, Leroux, the utero-vaginal inversion of Donné, the *corpus uteri* and *cervix uteri* are completely inverted and the anatomical limit, as indicated by Levret, is the vaginal insertion at the vulvar orifice. Under these conditions, the inverted uterus is also prolapsed and protrudes beyond the plane of the genital fissure.

In the case under consideration, the cervical canal was completely inverted on the right side, the cervico-uterine sulcus (Donné) had disappeared, the cervico-vaginal sulcus was shallow. On the left side, the cervico-uterine and cervico-vaginal sulci were perfectly distinct. In consequence of the complete inversion of the right half of the cervix the long axis of the uterine globe was sensibly deflected to the left of the median line. The vaginal portion of the cervix was short, and lacerated on either side to the vaginal junction. The inverted uterus was perfectly mobile, and no trace of inflammatory infiltration could be detected about the pelvic peritoneum or in the connective tissue. The position of the ovaries, tubes and round ligaments could not be mapped out with any degree of certainty.

(2) *Symptoms.* The writer thought it was fair to assume that the inversion of the uterus, in the case under discussion, occurred at the time of delivery. The weight of probable evidence is in favor of this assumption. The inversion must have occurred before

the third week following labor, because at that time the presence of an intra-vaginal tumor was discovered by the patient. This interval of three weeks was spent quietly in bed in the dorsal decubitus. The conditions for inversion would be at no time during this period so favorable as during or at the completion of the third stage of labor. During this period, no cause adequate to the result was in operation. On the other hand, during or at the completion of the third stage of labor, all the causes and conditions known to be necessary to the production of inversion were present, that is, the enlarged and relaxed corpus, dilated cervix, traction on the cord; possibly, also, fundal insertion of the placenta (Hennig), and paralysis of the placental site (Rokitansky). If this assumption be granted, the case demonstrates that inversion of the uterus may "take place without sufficient symptoms to attract attention, or to indicate that anything has gone wrong." Dr. J. C. Reeve has already called attention to this subject, and has sustained the proposition just quoted, by the citation of well-authenticated cases, in his classical essay, "Moot Points in Regard to Inversion of the Uterus."

The patient, a woman of at least average intelligence, and the midwife, a "qualified" practitioner, that is, examined and registered by the State Board of Health of Illinois, observed no symptoms sufficient to attract attention, or to indicate that anything unusual had happened at the time of delivery. A well-known and skilful obstetrician saw the case forty-eight hours after the probable time of the occurrence of the accident, and the absence of symptoms was so marked that the condition escaped his critical observation. Seventy-two hours after the probable time of occurrence of the accident, the patient was seen by another thoroughly competent medical man, who also failed to recognize the complication upon his first, or upon any subsequent visit.

Dr. Reeve's proposition has an important bearing upon the differential diagnosis between inversion of the uterus and sessile polypus, and indicate that no reliable evidence can be obtained from the history of the case.

(3) *Treatment.* Carl Braun, in 1851, introduced a simple, convenient, and safe method of the vaginal tamponade (colpeurysis) by means of a caoutchouc bag (colpeurynter). The reduction of chronic inversion of the uterus by colpeurysis was inaugurated by a communication from Tyler Smith to the Royal Medical and Surgical Society of London, April 13th, 1858. In this communication, Tyler Smith reports the reduction of a chronic inverted uterus by taxis in connection with continuous elastic pressure by means of Gariel's air-pessary. Barrier, of Lyons, in 1852, employed an air-pessary to retain the uterus in position, but with no avowed intention of using continuous elastic pressure to effect reduction, as intimated by Donneé. M. P. Teale, Jr., of Leeds, and West effected reductions of the inverted uterus in 1859 by Tyler Smith's method. It was reserved for Bockenthal, as remarked by Thomas, to demonstrate in the same year that reduction could be effected by the colpeurynter, unaided by taxis.

As a matter of practical import, the colpeurynter used in the case described was a quadrilateral, caoutchouc bag, ten cm. long, five cm. wide when collapsed, and possessing a maximum circumference of twenty-one cm. when distended. It is known in the shops as

"No. 5 pear-shaped water-pessary." The selection of a properly-shaped and properly-sized instrument demands some care. Dr. Byford's treatise is the only American text-book on gynaecology which gives an adequate exposition of colpeurysis as one of the methods of reduction of chronic inversion of the uterus. This fact may be interpreted as indicating that the method is not extensively practised in the United States, and a survey of American medical literature upon this subject will serve to confirm such an opinion. In the very large majority of cases, more heroic measures have been adopted. On the other hand, colpeurysis has largely replaced all other modes of treatment in Germany. Fritsch says: "Gradually, almost all gynecologists have gone over to Braun's colpeurynter." "The treatment with the colpeurynter is the sovereign method of treatment in cases of inversion of the uterus. Inversions yield to it which have resisted all other methods. The resistance which the cervix opposes may be so great that Muzeaux (quadrivalve) forceps inserted into the portico tear out, and still the uterus remains unmoved. If colpeurysis is now resorted to, earlier or later, a successful result is bound to follow, without the application of violence and without danger. It is, therefore, urgently advised to give up every attempt at forcible reposition of the uterus." He adds the significant sentence: "Colpeurysis cannot be held as without effect, even if the end is not immediately attained; it may be continued, with interruptions, fourteen days, yes, even three weeks." "The best method of treatment of chronic inversions," says Rheinstaedter, "is the introduction of a colpeurynter, which is gradually distended with water." Schroeder has repeatedly effected the reduction of the chronic inverted uterus after the failure of all efforts at manual reposition.

(The discussion on this paper is deferred to next week.)

— A certificate of disability, issued by Dr. A. Y. P. Garnett to a government employee, was returned by a United States pension officer, with the demand that the doctor should strengthen it with implicit information. Dr. Garnett declined to furnish this information, on the ground that it would involve the violation of professional obligations. In this decision he has been sustained by Secretary Lamar, who has thus established a precedent which petty courts and government officers will not presume in future to set aside.

— The Graefe medal, recently instituted by public subscription, in perpetual memory of Albrecht von Graefe, is awarded every ten years by the Ophthalmological Society, meeting annually at Heidelberg, to the man of whatever nation who may be designated as having rendered the greatest service to ophthalmology. The ceremony of the first presentation of the medal took place at the close of the Quincenary Festival of the University of Heidelberg, on the 9th of August, 1886, Professor von Zehender, of Rostock, presiding, in presence of the Pro-Rector, Professors, and many distinguished visitors. The medal was awarded to Professor von Helmholtz, and the oration on the occasion of its presentation was given by Professor Donders, of Utrecht. It is given in full in the *British Medical Journal* of December 11th.

THE BOSTON  
Medical and Surgical Journal.

THURSDAY, JANUARY 6, 1887.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 283 Washington Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES, UPHAM & COMPANY,  
283 WASHINGTON STREET, BOSTON, MASS.

### SEVERED DIGITS.

DURING the last few months the JOURNAL has contained several communications in regard to the reunion of portions of fingers severed from which they had been completely severed. Five different physicians have recorded ten cases which have fallen under their own observation; eight in the reporter's practice and two in the practice of the reporter's father. Of these ten cases four are reported as perfect; three cases were successful but there was more or less impairment of sensation; one lost half the last phalanx by sloughing; two only can be considered as failures, both of them united but one afterwards separated, the other shrivelled and was practically worthless. We have also quoted during the same time a case from a Russian surgeon in which a portion of a thumb became reunited with perfect sensation but limited motility, and this week's JOURNAL contains another equally well-authenticated case occurring in domestic practice.

That as large a number of cases should be reported in so short a time is quite surprising. It establishes however, the fact that reunion is possible: a fact in opposition to the former belief of the majority of the profession. The cases reported are, with two exceptions, all successful; how great a proportion they would bear to the utter failures it is impossible to guess, but twelve cases in which some sort of adhesion has taken place, are enough to warrant much more careful attempts to restore small portions of the body which have been accidentally amputated.

The fingers most suitable for preservation, or those most likely to reward the attempt, would seem to be those which have been removed by a clean cut, so that suppurative union between the two portions may be avoided. The time which may elapse between the accident and the successful replacement of the separated portion would seem to be very long. In Dr. Nivison's case three or four hours had elapsed during a portion of which time the fingers had been covered by snow. In these successful cases great care was evidently

taken to secure perfect cleanliness of the cut and careful apposition of the fragments together with such other care as seemed likely in the eyes of the surgeon to secure union without suppuration.

The literature of the subject is evidently not very large; still a very considerable number of reported cases are accessible, of fingers and other portions of the body, which have reunited after separation. An interesting case, for the fulness of detail with which it is reported, is that of Dr. Goschler, in the *Wiener Medizinisch Wochenschrift* for 1868. A man of sixty chopped off nearly the whole of the last phalanx of the ring finger, preserved the fragment for three-quarters of an hour in water at a temperature of 11° Réaumur. In thirty-six hours there was evidently agglutination, during the third, fourth and fifth days the extremity was cold, but adherent and evidently sensitive. On the ninth day the reunion of the soft parts was assured, but there was no union of the bony fragments. At the end of a month recovery was complete.

### EXPERIMENTS IN TRAP SIPHONAGE AT THE NAVY MUSEUM.<sup>1</sup>

REPEATED experiments on trap siphonage have shown beyond question that the ventilation of soil-pipes and traps is a safeguard against the entrance of sewer gas into dwellings except in unusual contingencies, provided the general plan of the drainage and sewerage is correct and the workmanship good. The experiments at the Navy Museum in Washington have confirmed the results of those reported to the National Board of Health by Philbrick and Bowditch, and are stated in the following terms:

- (1) The seals of ventilated traps are safe against siphonage and back pressure.
- (2) The seals of unventilated traps are never safe from siphon action or back pressure, except in deduction four.
- (3) The vertical vent should be three inches, with a four-inch soil-pipe.
- (4) Traps connected on a horizontal pipe and fixtures discharging on the same level into horizontal pipe apparently have no effect on unventilated traps.
- (5) All varieties of non-mechanical traps are more easily affected by back pressure than by siphonage.
- (6) The ball-traps were not affected by back pressure, but by siphonage.
- (7) The Sanitas trap withstood siphon action better than any of the patent traps, but was easily affected by back pressure.
- (8) The sewer air is more liable to enter unawares by back pressure through the seal of the trap, because the seal remains unbroken.
- (9) Difference in friction of iron and lead pipes made no apparent difference in the effect on the traps.

<sup>1</sup> Report on Experiments in Trap Siphonage at the Museum of Hygiene, United States Navy Department, Washington, D. C. By Glenn Brown, Architect. Washington: Judd & Detweiler, Printers, 1884.

We are left in the dark, however, as to the precise nature of the unusual contingencies under which it is admitted that ventilated traps may be siphoned out and the emanations from the sewers enter houses; and Putnam and Waring think that they have shown that the so-called unusual conditions may occur where not in the least suspected, although a patent trap and water-closet intended to meet these "unusual contingencies" might perhaps serve as a bias against entirely unprejudiced judgments in the case.

It is true, however, that the approved methods of plumbing are now so costly as to make them practically unattainable to many householders, and that, outside of a very simple system of plumbing for moderate-sized houses, it is difficult to know with certainty what is safe and what not. The Museum of Hygiene, under the Navy Department, has an excellent opportunity to show just what the conditions are by which water-closets and soil-pipes inside a house may be made free from danger, and, it is to be hoped, that this will be done, no matter what the cost of time or money. If plumbing can be simplified and cheapened at the same time, the benefit to society will be incalculable.

#### CEREBRAL SYPHILIS.

DURING the past year various publications on the subject of Cerebral Syphilis have appeared which are well worthy of notice.

The view that syphilis rarely attacks the brain substance itself but rather the membranes, the sheaths of the vessels that arise from the pia, and especially the arachnoid at the base of the brain, from the optic chiasma to the pons, finds support from Gerhardt.<sup>1</sup> In the majority of his cases the first symptoms appeared at least five years after infection. Mental overwork, alcohol, and disordered living lead to cerebral congestion, and thus aid the development of syphilitic disease. Traumatism is an important exciting cause, and so, to a less degree, is emotional excitement. In many cases a diagnosis can be made without a previous history of infection, which should be our aim. Repeated apoplectic attacks in young persons without any cardiac disease, ocular paralyses, ptosis, epilepsy coming on after childhood without known cause, cortical epilepsy, monoplegia, acute bulbar symptoms, and inexplicable symptoms of hernia are all important in diagnosis. Apoplexy is common; it usually comes on slowly with prodromata, from an advancing thrombosis. A gumma does not cause the signs of a massive tumor like glioma. More cases are detected now than formerly, and the diagnosis can be made earlier, hence more recover, as the early stages are curable. The treatment should be early and energetic, and should be kept up as long as possible. Gerhardt thinks we ought now to improve on Fournier's data in prognosis, that one-third get well, one-half improve, and one-sixth die.

<sup>1</sup> C. Gerhardt. Ueber Hirnsyphilis. Berlin, kl. Wochenschrift, Nr. 1, 1886.

Amidon<sup>2</sup> thinks that the importance of syphilis as a cause of nervous disease has been over-rated, because alcohol, tobacco, excess, worry, etc., are overlooked. Many obscure cases are not syphilitic, although there is a history of syphilis. A gumma is curable, but, if not treated, may cause pathological conditions, which will not yield to subsequent treatment. He cites ten cases, in which the period of incubation averaged nine years. Three cases showed symptoms of periencephalitis, secondary to the syphilitic lesion. Endarteritis may be cured, but not the thrombotic softening following it. A frank growth yields more easily. The late lesions of syphilis are local or diffuse, and not systemic, and hence in Dr. Amidon's opinion *tuberc dorsalis* is not a syphilitic disease. The treatment must be prompt and persistent; and when the early symptoms appear, such as headache, neuralgia, vertigo, insomnia, vesical weakness, sexual excitement, etc., the patient should at once consult a physician.

Lays<sup>3</sup> had stated as an interesting and previously unknown fact, that in doubtful cases of cerebral syphilis he has found little sclerosed nodules, which can be felt on the cut surface of the pons and basal ganglia.

#### THE GASEOUS MEDICATION, PER RECTUM, OF PULMONARY DISEASES.

THE latest novelty in therapeutics comes from a Frenchman, Bergeon by name. The "new medication" consists in treating certain pulmonary diseases attended with cough (chronic bronchitis, whooping-cough, phthisis, etc.) by rectal injections of certain gases, which are readily absorbed and eliminated by the lungs, such as carbonic acid, sulphuretted hydrogen, and sulphide of carbon. These gases, at the moment of elimination, are believed to have a favorable modifying influence on the diseased mucous membrane, promoting the resolution of inflammation, the healing of ulcerations, and wonderfully diminishing cough and expectoration.

It has long been known that certain medicines given in pulmonary complaints for the relief of cough, such as copaiba, turpentine, and carbonate of ammonia, largely owe the benefit which frequently attends their use to the modifications which they effect on morbid states of the pulmonary mucosa, while being eliminated by that emunctory. It has been known, too, that various gases, such as those above mentioned; when absorbed by the venous system, also pass out in the air of expiration.

It was, many years ago, proposed to treat diseases of the lungs by causing patients to respire medicinal vapors, and many have been the attempts made to fulfil this indication, with, however, but indifferent success; the medicated vapors, as ordinarily inhaled, were found not to penetrate very deeply, and to be far less diffusible than was thought *a priori* to be the

<sup>2</sup> R. W. Amidon. On the Incurability of Certain Nervous Affections occurring among Syphilitics. Medical News, January 16, 1886.

<sup>3</sup> Des Syphilomes de l'encéphale. L'encéphale, January, 1886.

case; some gases, as carbonic acid and sulphuretted hydrogen, could not be respired with impunity. It remained for M. Bergeon, basing himself on some experiments of Claude Bernard, to show the practicability of the treatment of pulmonary diseases by causing these latter gases to be absorbed by the rectum. This method, according to M. Bergeon, has also another advantage, namely, that of distributing the medicament throughout the entire pulmonary mucous membrane, and thus ensuring its contact with such parts as are diseased.

The method employed by M. Bergeon is quite simple; he makes use of a mixture of carbonic acid and sulphuretted hydrogen. Pure carbonic acid, generated on the spot from *cartouches* containing an exact quantity of tartaric acid and bicarbonate of soda, is conveyed into a rubber bag of just the capacity of four liters; the latter is connected by suitable tubing, with a rubber-ball injector which is worked by the hand, and which also makes part of a rectal tubing and canula, resembling that of a Davidson syringe. The rubber bag is filled with carbonic acid, which flows into it from a glass-generator, in which the contents of the *cartouche* are dissolved; the gas, before being injected, is made by an ingenious device to pass through a glass flask or *barboteur* containing a solution of sulphuretted hydrogen, where a blending of the two gases takes place, and it is this gaseous mixture which is utilized for injection. It has been found by M. Bergeon that no other solution of sulphuretted hydrogen gives so satisfactory results as natural mineral waters, particularly the *Eaux Bonnes* of the Pyrenees.

Apparatuses for the manufacture *in loco* and therapeutic application of this new remedy are now for sale by the instrument-makers of Paris. The directions given for the use of the apparatus are as follows: "Only one, or, at the most, four liters of the gas are used on each occasion. The injection must be made slowly and without force, and it is necessary to leave an interval of from ten to fifteen seconds between the successive pressures made on the rubber ball, and to allow about half an hour for the entire operation. One, or, at the most, two injections (or 'séances') are practised per day.

Bardet, in the *Journal Nouveaux Remèdes*, and Dujardin-Beaumetz in the *Bulletin Général de Thérapeutique*, have reported the results of several trials of this new system of pulmonary therapeutics in the Hospital Cochin. "All agree," they say, "as to the signal benefits derivable from this treatment. In chronic bronchitis of whatever nature, the three following modifications are constantly obtained: diminution and rapid modification of the expectoration, diminution of the cough and of the oppression; there ensue, as a consequence of this amelioration, better sleep, better appetite, and an augmentation of weight." These gaseous rectal injections are said to be generally well tolerated, when slowly and carefully made. In pulmonary phthisis, it is claimed that marked amelioration has been obtained.

Dr. J. Henry Bennet gives, in the *British Medical Journal* of December 18, 1886, an account of his personal conversation with the inventor of this new process of medication, and while claiming to have heard of it at first only with incredulity, he ended by acknowledging its reasonableness in theory, and its efficacy in some cases in practice. In a lecture which M. Bergeon gave upon the subject to a score of the physicians of Mentone, he claimed that the failures which have resulted from the process have been due merely to faults in its performance. Thus, if the bag of carbonic acid is not scrupulously emptied and freshly filled before each operation, some atmospheric air will penetrate it, and, being injected, will cause intestinal pain and irritation. Not only is air an irritant to the bowel, but so are other chemical agents that have been tried, as chlorine, turpentine, ether, and ammonio-bromine, some of which even produced gangrene in the animals on which they were tried. Dr. Bennet was much impressed by the relief given to an aggravated case of asthma by the injections.

We shall await with interest the results of further trials in the Parisian hospitals of this new method of treating pulmonary diseases; it is not a mode which is destined rapidly to become popular, in this country, at least, nor will it be likely soon to come into favor with physicians in private practice.

#### MEDICAL NOTES.

— A contemporary points out the fact that of the fifty-five signers of the Declaration of Independence, five were physicians.

— According to the *Medical Record*, London has only 90,000 paupers, according to its census, yet it treats in free hospitals 1,000,000 of patients annually, at a cost of \$2,500,000. Its annual hospital deficit is \$250,000.

— "Pneumatic differentiation" seems likely to mean differences between manufacturers of the pneumatic cabinets. The Pneumatic Cabinet Company of New York, announces that they will prosecute every physician using any other cabinet than the one they manufacture.

— The *Maryland Medical Journal* says that a very poor and aged white woman was murdered on November 10th, at her home in Baltimore, by two colored men named John T. Ross and Albert Hawkins. The object of the murder was to get fifteen dollars for the body of the victim. Anderson Perry, well-known to many of the recent graduates of the University of Maryland, first as a ward-master at the infirmary, and more recently as an attendant in the dissecting-room at the University, is charged as an accessory to the crime. The murder was conceived and executed in the most premeditated and cold-blooded manner.

— *Truth*, November, 1886, makes the following comment upon the infallibility of analysts. "Six samples of beer were to be sent to Guy's Hospital for analysis;" and in the presence of Councillor Taylor,

a member of the Food and Drugs Committee, and a professional chemist, "a large quantity of a most deadly poison" was placed in one of the samples by way of checking the analysts. The report on this sample was: "I am of opinion that this sample of beer is genuine." The experts subsequently explained in their own defense "that the above result is perfectly natural, inasmuch as an analyst can only test for what he has reason to suspect."

— We find in a Western contemporary a quotation from a Boston letter to the *New York Tribune* which paints a very glowing picture of the openings for female physicians in Boston. The writer says that "a properly educated woman physician can secure in Boston a paying practice within one year." It is further affirmed that there are nine women physicians who have the "swell practice" of Boston. These have been in practice from five to twenty-five years, and have incomes ranging from five to twenty thousand dollars a year. Whether these are all "properly educated" physicians is not stated. If so it would be money in the pocket of a medical man if he could be born a female.

## BOSTON.

— The melodramatic suicide of two young women recently, by means of that common article of "domestic consumption," "Rough on Rats," calls attention again to the folly of allowing the sale of deadly poisons without restrictions. It is very generally known that "Rough on Rats" contains arsenic in large quantities, and it is still more generally known that it can be purchased from grocers or apothecaries, no questions asked, by any one having the few cents to pay for a box. If a servant girl, otherwise known as the "lady-help," thinks she is not treated with a sufficiently distinguished consideration, she puts a box full of "Rough on Rats" in the flour barrel or in the family tea-pot; two such actual cases have been commented on in these columns within a year or two; if a young woman has a jealous "tiff" with a lover after dinner on Christmas evening she puts half a box of the compound into her own stomach; and most startling of all, another young woman swallows a full box out of mere sympathy and affection for her friend and companion. We shall take occasion to revert to this subject again.

## NEW YORK.

— The receipts reported up to Friday, December 31st, from the Annual Hospital Saturday and Sunday Collection, which was made December 24th and 25th, amount to \$13,146.54.

— The Brooklyn Health Department estimates the present population of that city, based upon the returns from various municipal departments, at 745,108, an increase of 35,108 since July 1, 1886.

— On Thursday morning, December 30th, an extra meeting of the Academy of Medicine was held, when Dr. F. H. Bosworth read a paper on "Deformities of the Nasal Septum": A new operation for its correc-

tion, with an analysis of its results in 160 cases, as throwing new light on the pathology of intra-nasal diseases, and their relation to laryngeal and bronchial affections, hay fever, asthma, and other so-called nasal reflexes.

— The fair which was recently held at the New Central Park Garden in aid of the Montefiore Home for Chronic Invalids, a Jewish institution, was attended by over seventy thousand visitors, while the receipts amounted to more than \$160,000.

— A peculiarly sad case is reported from the German Hospital at Newark, N. J., where Dr. Anatol Roessler, the house physician, died from diphtheria, December 30th, having contracted the disease one week previously from a child suffering from it, in whose case he had performed tracheotomy. Dr. Roessler was born in New York in 1862, and his mother, who is a widow of limited means, and whose only child he was, had made many sacrifices in order that he might be enabled to pursue his medical studies. He was a graduate of Bellevue Hospital Medical College, and only received the appointment as house physician to the hospital in Newark on the 1st of December last.

— The Superior Court, Justice Sedgwick presiding, last week rendered a decision which has been received with much gratification by the entire profession. This reverses the judgment in the case in which Angelina M. Brown obtained \$500 damages from Dr. Purdy, on the allegation that he had caused her to be placed in the small-pox hospital on Blackwell's Island when she was not suffering from this disease. Judge Sedgwick holds that there was no ground of action against the defendant, and states that it was the doctor's duty to report the case if he believed it to be of an infectious nature. He furthermore decides that the defendant was not, under any circumstances, liable, as the plaintiff was sent to the small-pox hospital by the sanitary inspector who had charge of the investigation of the case.

— The report of Dr. John T. Nagle, of the Bureau of Vital Statistics, shows that in the past year there were 31,819 births, 12,216 marriages, and 37,330 deaths in the city, an increase of 1,289 births, 500 marriages, and 1,648 deaths over the previous year. The deaths from zymotic diseases numbered 9,657; from constitutional diseases, 8,210; and from local diseases, 15,817. There were 1,466 violent deaths, 31 deaths from small-pox, one from yellow fever, 775 from measles, 1,731 from diphtheria, 370 from scarlatina, 966 from membranous croup, 576 from whooping-cough, 324 from typhoid fever, 14 from typhus fever, 369 from puerperal diseases, 211 from alcoholism, 778 from cancer, 1,707 from bronchitis, 3,665 from pneumonia; heart diseases, 1,892; sunstroke, 42; apoplexy, 761; and kidney diseases, 2,214. There were 224 suicides — 173 men and 51 women — of whom 99 were Germans and 59 native born.

Of the deaths reported, 2,495 were of persons over

70 years of age, and five over 100 years. The deaths of children under one year numbered 9,871, and those of children under two years, 13,064. The deaths of children under five years were 43.3 per cent. of all deaths, numbering 16,151, against 15,267 in 1885, and 17,520 in 1882. Diphtheria was the most fatal zymotic disease of the year. Of the total number of deaths, 7,136 were in institutions, 21,454 in houses containing over four families, and 526 in the streets or rivers. Of the 31,319 births, 16,191 were males, and 15,127 females. The foreign-born mothers numbered 19,058, and native mothers, 12,259. One foreign-born mother bore her twentieth child, and one native mother her twenty-second child.

### Miscellany.

#### THE MEDICAL AND MEDICO-LEGAL FACTS IN THE COLIN CAMPBELL CASE.

THE Colin Campbell case has really amounted to something more than a newspaper *bonne-bouche*, having involved, as we learn from the medical facts published in the *Medical Press*, a question at once novel and important in forensic medicine. At the first trial, wherein Lady Colin obtained a decree of judicial separation, which decree on appeal to a higher court was reaffirmed, it was shown in evidence that before marriage the husband had been suffering from perineal abscess, the sequel of gonorrhœa contracted some few years previously, for which abscess he had undergone one or two surgical operations — namely, perineal section into the urethra. Marriage took place before the parts were restored to health, but it was previously agreed that separate beds should be occupied for two months or so in order to permit of recovery. The contention of the wife was that although he had been operated upon and was not as yet recovered at the time of marriage, yet she had no idea he was suffering from any disorder of the genitals, but had thought it was something of the nature of piles. Communications had been made to her by medical men, but she asserted that this was thus understood by her. However, after some time permission was given to commence intercourse; but as the husband was again laid up it had to be discontinued, and further operations became necessary. Intercourse was occasionally resumed, but ultimately the wife's health was affected, and it was found she was suffering from irritation of vagina and vulva, with uterine leucorrhœa. Local applications were made to the vagina and cervix uteri, but without much benefit. Dr. Braxton Hicks was called in after an attack of very severe pain on one side of the pelvis, who found there a cellulitic effusion; after a few weeks this subsided, but still the uterine catarrh remained with much irritation of the vagina. As the canal had been well medicated without benefit, the os was dilated. It was evident that the uterine cavity was larger than normal. A silver tube was passed, through which the interior of the uterus was painted over by a brush charged with iodized phenol. This cured the complaint. However, upon overtures being made by the husband for renewal of cohabitation, she begged him to refrain in future, he being still uncured, and to occupy a separate bed. He said if

this was to be the case he would leave her; but she rejoined that if so, she must make clear the reason. Hence this action for separation. And the question asked the Court was whether under these circumstances it was obligatory on a wife to permit cohabitation; and, if not, then an order in her favor was requested. Evidence having been taken on the above-mentioned facts, the question put by the Court to many witnesses was whether the endometritis and other symptoms from which the wife suffered were likely to result from coitus where purulent secretion found its way into the urethra. It was then stated by several medical men, that although there were many causes which produce like symptoms, it was a result quite to be expected under the circumstances. The result of the evidence on his part was to confirm the cause and circumstances of his illness and severe operations, as above described, and the jury (special) after a brief consultation found that the husband had been "guilty of cruelty," which was the legal form of the plaint, and the Court decreed a judicial separation. An appeal was granted. The husband argued the case in person, but the upper Court confirmed the decree of the Court below. No similar case had been in the Divorce Court before, and in any way the decision in its principle was important.

#### YELLOW FEVER INOCULATION BY ONE OF THE PROTECTED.

OUR readers will recall the interesting communication by Dr. Lane, of Brazil (*JOURNAL* June 10, 1886), on Freire's yellow fever inoculations. We find in the *Lancet*, November 6, a description, summarized from the *Journal de Médecine de Bordeaux* of the observations and experiments of Dr. Freire by Dr. R. Issartier, surgeon in the Messageries Maritimes, who has submitted himself to Dr. Freire's anti-yellow fever inoculation. The microbe found in all the fluids of persons and animals dead of yellow fever, in their vomit, and even on the walls of yellow fever wards and in the earth of the cemetery, is named *Cryptococcus xanthogenicus*. Wherever it existed it served to inoculate animals, and a guinea-pig kept in a confined space containing a jar of fresh earth from the cemetery, very soon died, while other guinea-pigs kept in a similar space with the same earth, sterilized by heat, remained sound. A series of animals could be inoculated from one another, and the virus appeared to lose nothing of its activity by transmission, so that Prof. Freire had to try some other plan for attenuating it for "vaccination" purposes. This he succeeded in doing by means of gelatine cultures in Pasteur's flasks. After the seventh culture guinea-pigs inoculated with the attenuated virus appeared to suffer only a slight indisposition, instead of dying, as those inoculated with each of the preceding ones did. The writer and a number of other medical and lay persons, together with Dr. Freire himself, were inoculated or "vaccinated" with the seventh culture, and none of them experienced more inconvenience than slight headache and transient malaise. They were subsequently proved to be quite unaffected by much more virulent cultures. Dr. Issartier states that the yellow fever mortality among the protected persons in Rio was 1.6 per cent., while among the rest of the population it was 13.7 per cent.

## Correspondence.

## SEVERED DIGITS.

BEVERLY, MASS., Dec. 24, 1886.

MR. EDITOR,—In a letter dated "Burlington, Feb. 24, 1840," from Professor Joseph Torrey to Dr. Augustus Torrey, I find that domestic surgery has been successful in repairing severed digits.

"My eldest son, Joseph, a few days since, cut off the end of his thumb, taking about half the nail, with a hatchet. He left the piece among some shavings, on the floor. After a little search I found it still warm; his mother fixed it on with sticking plaster, and it has grown as firm and even as if there had been no cut at all." An

extract from a letter written me lately by the patient above alluded to, says: "The healing was perfect, and for many years the line of the cut was quite distinct. Now it is just visible, though it seems much nearer the end of the thumb than it did when I was a boy. I don't think the detached portion has ever grown much, though the end of the thumb is entirely symmetrical. That is, without increasing in size, the little piece has adapted itself in shape to the place, so that what was once quite a considerable fraction of my *big* thumb has become the proportionally much smaller terminus of the man thumb.

It was when I was seven years old, and I well remember the whole scene—including the *lint* in which it was done up for some days before the bandage was removed."

Respectfully yours, S. W. TORREY, M.D.

## REPORTED MORTALITY FOR THE WEEK ENDING DECEMBER 25, 1886.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Deaths reported 2,082; under five years of age 736; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 368; consumption 290, lung diseases 384, diphtheria and croup 140, measles 98, diarrhoeal diseases 32, scarlet fever 24, typhoid fever 23, malarial fevers 19, whooping-cough seven, erysipelas 14, cerebro-spinal meningitis five, puerperal fever four. Small-pox (Brooklyn) two. From scarlet fever, Brooklyn nine, New York eight, Pittsburgh four, Cincinnati two, Haverhill one. From typhoid fever, Boston five, Cincinnati four, New York three, Brooklyn, Baltimore and New Orleans two each, Worcester, Lowell and Lawrence, New Bedford and Fitchburg one each. From erysipelas, New York five, Baltimore and Charleston two each, Brooklyn, Boston, Cincinnati, New Orleans and Taunton one each. From malarial fever, Brooklyn eight, New Orleans five, New York four, Nashville and Lawrence one each. From whooping-cough, New York, Brooklyn, and Boston two each, Pittsburgh one. From cerebro-spinal meningitis, New York four, Boston one. From puerperal fever, New York, Boston, Lowell and Taunton one each.

In the 18 cities and greater towns of Massachusetts, with a population of 943,470 (population of the State 1,941,465) the

total death-rate for the week was 20.50 against 21.05 and 23.05 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,065,817, for the week ending December 11th the death-rate was 22.9. Deaths reported 3,984; infants under one year of age 975; acute diseases of the respiratory organs (London), 494; measles 181, scarlet fever 65, whooping-cough 60, fever 50, diarrhoea 35, diphtheria 32, small-pox (Leeds) one.

The death-rates ranged from 33.3 in Wolverhampton to 12.1 in Brighton; Birmingham 18.0; Bradford 20.7; Hull 17.7; Leeds 25.7; Leicester 22.0; Liverpool 25.2; London 21.9; Manchester 29.2; Newcastle-on-Tyne 25.2; Nottingham 19.9; Sheffield 24.8.

In Edinburgh 17.0; Glasgow 26.9; Dublin 35.6.

For the week ending December 11th, in the Swiss towns, there were 34 deaths from consumption, lung diseases 21, diarrhoeal diseases 17, diphtheria and croup nine, measles four, whooping-cough one, erysipelas one.

The death-rates were: at Zurich 7.6; Geneva 20.2; Basle 14.8; Berne 37.4.

The meteorological record for the week ending December 25, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole of the United States Signal Corps:—

Week ending Saturday, Dec. 25, 1886.	Barom- eter.	Thermometer.			Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM DECEMBER 25, 1886, TO DECEMBER 31, 1886.

KOESPER, EON A., major and surgeon. Granted leave of absence for two months, to take effect about January 1, 1887. S. O. 297, A. G. O., December 27, 1886.

PHILLIPS, JNO. L., first lieutenant and assistant surgeon. Granted one month's extension of his leave of absence. S. O. 297, A. G. O., December 27, 1886.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE WEEK ENDING JANUARY 1, 1887.

ANDERSON, F., passed assistant surgeon. To United States Steamship "Metis."

AUZAL, E. W., assistant surgeon. Detached from Revenue Steamship "Independence," and ordered to Coast Survey Steamer "McArthur."

GRIFFIN, E. H., passed assistant surgeon. Detached from Naval Laboratory for temporary duty on Revenue Steamship "Independence."

GATEWOOD, J. D., passed assistant surgeon. To Naval Academy, January 5, 1887.

#### SOCIETY NOTICES.

MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT.—THE SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE will meet at 19 Boylston Place, on Wednesday, January 12, at 7.45 o'clock. A debate upon "Poisoning by Arsenical Wall Papers," will be opened by Dr. J. B. Chadwick. Drs. S. W. Abbott and H. P. Walcott, of the Massachusetts State Board of Health, Prof. E. S. Wood, Prof. E. J. Young, Prof. H. P. Bowditch, Prof. W. B. Hills, and Prof. Lyons, of Harvard University, Dr. J. M. Harlow, of Woburn, Drs. E. C. Stedman, F. H. Brown, and F. W. Draper, Mr. Gregory, and Mr. J. P. Bumstead. Paper-Dealers and others are expected to take part in the discussion.

ALBERT N. BLODGETT, M.D., Secretary.  
F. L. KNIGHT, M.D., Chairman.

GYNECOLOGICAL SOCIETY OF BOSTON.—The annual meeting of the Society will be held at No. 19 Boylston Place on Thursday, January 13, 1887, at 4 o'clock, P. M. Communications: a paper by Dr. Apostoli, of Paris, entitled, "A New Method of Treatment of Chronic Metritis—and especially Endometritis—by the Intravaginal Chemical Galvano-Cautic," will be read by Dr. L. R. Fox, of Lowell. President's Address by Dr. H. O. Marcy, "Recent Advances in Abdominal Surgery." Refreshments will be served after the meeting.

H. J. HARRIMAN, Secretary.

#### OBITUARY. HORATIO NELSON SMALL, M.D.

Died in Portland, Me., December 29, 1886, Horatio Nelson Small, M.D., aged forty-seven. For many years their associate in the medical profession, having been removed from their midst by death, the physicians of Portland, desiring to give public expression of their estimate of his character and of their

grief at his loss, make the following statement of their sentiments:

Dr. Small justly occupied a foremost place among the practitioners of his region. Devoted to the interests of his patients, remarkably successful in ministering to their infirmities, cheering and sustaining them in their despondency, he quickly won the confidence and affection of a large clientele. As an obstetrician he easily took the lead, and was, in this capacity, alike valued by patients and physicians. In every position of trust and responsibility to which he was called—as army officer, examiner of pensioners, teacher, practitioner, husband, citizen—his conduct was marked by the qualities which ever distinguish a pure, noble, and exemplary life. But, while these traits compelled respect and admiration, the characteristics for which he will be longest and most tenderly remembered was the abounding kindness of spirit, which endeared him to all who knew him well. Equally to the dreary hovel of the poor and the sick-chamber of the rich he came like a beam of sunshine. The cheerfulness of his face and voice was but the manifestation of his happy disposition, and made him always welcome in every company. Even when feeling deeply wronged, he was slow to attribute sinister motives, and displayed hardly a trace of disturbance or serenity. The older of his fellows held him as a wise and faithful counselor, and to the younger he was a willing and generous support in their troubles. All his brethren unite in mourning his untimely fate, and will ever fondly cherish the memory of his sweet nature as a precious heritage.

FREDERICK H. GERBISH,  
AUG. S. THAYER,  
CHAS. O. HUNT,  
Committee.

#### APPOINTMENT.

Dr. Richard L. Hodgdon, of Arlington, and Mr. C. C. Coffin, of Boston, have been appointed members of the Massachusetts Board of Lunacy and Charity.

#### BOOKS AND PAMPHLETS RECEIVED.

The Contagious and Parasitic Diseases of Animals. Issued by the State Board of Health of Maine.

Circulars of Information of the Bureau of Education. No. 1, 1886. The Study of Music in Public Schools. Washington. 1886.

Gout and its Relations to Diseases of the Liver and Kidneys. By Robson Roose, M.D.F.C.S. Third Edition. London: H. K. Lewis. 1887.

A CASE OF LAPAROTOMY FOR RECENT ADHESIONS OF THE INTESTINES TO THE ABDOMINAL PARIETES: RECOVERY.<sup>1</sup>BY GEORGE W. GAY, M.D.  
Visiting Surgeon, Boston City Hospital.

The following case is reported not so much on account of its favorable termination, as for the valuable hints it gives us for our guidance in the future. Laparotomy for recent peritoneal adhesions is not so common an operation, but that each case is of interest and value in helping to establish the best method of treatment. There comes a time in many of these cases when little benefit can be expected from medicine; how much may be expected of surgical treatment is to be determined only by the crucial test of experience, and I herewith contribute my mite for what it is worth, being fully aware that few, if any, conclusions can be drawn from a single case.

Although Frank R. was only fourteen years of age when he was taken sick, yet he weighed 150 pounds, and was strong and rugged in proportion. He worked in a cordage factory, where it was his business to carry bundles of bobbins weighing about fifty pounds. On the 27th of August, 1886, he got up in the morning feeling as well as usual. He went to stool, and contrary to his usual custom, he then passed an enormous quantity of flatus, and was immediately seized with a severe pain in the abdomen to the right of the umbilicus. The stool was free and easy, and the boy went to his work, but remained only about an hour on account of the severity of the pain. Soon after patient arrived home he was seen by Dr. W. H. Emery, who was obliged to give him three subcutaneous injections of morphia to alleviate the pain. The patient was fairly comfortable through the night but the next day the abdomen was tympanitic and tender all over. Morphia in moderate doses was required. Twenty-four hours later the tympanites had disappeared, and a bunch was discovered about three inches in diameter situated to the right of the median line just below the navel. It was prominent to touch and sight, movable, and tender. The treatment consisted mainly of morphia, fomentations, and poultices. The temperature ranged from 101° to 102°+, and the pulse from 92 to 100. Little vomiting. Bowels were constipated for first four days only; afterwards they were free, and at times rather too much so. The tumor increased for a week, when it had nearly doubled in size. It then slowly diminished, and the pain gradually disappeared.

Two months from the beginning of the attack (September 11th), I saw the patient with Dr. Emery. He had been quite free from pain for several days until that morning, when, with no apparent cause, it had returned and was more severe than ever. The patient had lost flesh and strength, was confined to the bed, had lost his appetite, and was beginning to vomit. Bowels were free and regular.

The seat of pain was confined to a spot about four inches in diameter, located to the right of, and a little below the umbilicus. While there was no distinct tumor to be felt, yet the abdomen was more prominent at that point than elsewhere. It was quite tender and the resonance was nearly or quite normal. There was

no fluctuation or edema, or enlarged veins. The affection evidently involved the deeper structures. The pain corresponded to the peristalsis of the intestines, and during their action the coils could be seen through the parietes. From the location and character of the pain I concluded that the intestines were attached to the abdominal wall, but that the adhesions did not encroach upon their calibre to any extent was evident from the fact that the stools were of normal frequency and quantity. A blister was applied to the affected spot, followed by poultices, and morphia was given under the skin in considerable doses to control the pain.

Despite this treatment the patient grew rapidly worse. Pain and restlessness increased, and were only partially relieved by large doses of morphia. Hiccough began to manifest itself, and all the symptoms tended toward destruction. On the fourth day of the relapse (September 14th), the patient's condition was so deplorable, that little benefit could reasonably be expected from a further trial of medical treatment, and the question of surgical interference demanded consideration and decision.

If the diagnosis was correct what would be gained by cutting into the peritoneal cavity and breaking up the adhesions? Would they not at once re-form, either in the same place or elsewhere? They do not, as a rule, after ovariectomy, why should they in the case under consideration?

Again, as it would be a difficult matter to separate all the adhesions of the various coils of intestines with each other, would not their contraction, as time went on, produce stricture with even more severe and obstinate obstruction than had yet taken place? With all due respect to the future it seemed to me that the present condition claimed the benefit of all our resources, and hence I advised an exploratory operation. The family physician strongly seconded the advice, and finally the parents consented. The patient was immediately removed to the City Hospital, and the operation performed under antiseptic precautions.

Either having been given and the boy surrounded by hot-water bottles, and covered well with blankets, an incision about two inches long was made on the median line just below the navel. The peritoneal cavity was opened, and a very little fluid escaped. The intestines were found to be adherent to the parietes over a space four or five inches in diameter corresponding to the sensitive spot on the surface. With the fingers the bowels were slowly and carefully separated from their unnatural attachments without doing unnecessary violence. The adhesions were quite firm in only one small spot, elsewhere they gave way readily. The hæmorrhage was of little consequence, and no ligatures were required. Two or three "sweepers" (small sponges) sufficed to free the peritoneum of blood, and the wound was closed by two sets of sutures; a continuous one for the peritoneum, and interrupted ones for the other structures. No drainage-tube was required. The standard dressing of the hospital, iodoform, absorbent gauze, and sheet-wadding was applied, and the patient put to bed.

He rallied well from the operation and had little vomiting, but he was restless and had some considerable pain through the night. The pain, however, was more controllable than previous to the operation. The next day there were marked signs of improvement. The bowels moved freely and much less morphia was

<sup>1</sup> Read before the Boston Society for Medical Observation, November 1st, 1886.

required. Two days after the operation the look of suffering and anxiety had disappeared and he was very comfortable. Took food well without nausea or vomiting. Bowels moved four times, not much pain. Opium was omitted on the third day, and he could lie on the right side, but not on the left without a dragging sensation. The wound was examined on the fifth day and found to be united. The superficial sutures were removed twenty-four hours later. They came out perfectly dry, their being no suppuration in their track. Tympanites gave no trouble after operation, the passage of flatus being free. The pulse and temperature came down to normal on the third day and has remained there. All through his convalescence the patient was troubled more or less with diarrhoea. Bismuth, calomel and opium did little good, but it improved greatly under the use of small doses of castor oil, and finally ceased.

Ten days after the operation there was a good deal of pain in the bowels for one day, which in the light of subsequent events I am inclined to ascribe to the peritoneal suture. In the course of a month the end of the deep suture appeared at the orifice of a small opening in the wound, and was removed. The silk had not been properly prepared, and hence it ulcerated out.

Six weeks after operation the wound was soundly closed, and the patient was up and about the ward feeling "first-rate," as he expressed it. Bowels regular, appetite good, and flesh and strength fast returning. The scar was an inch and a half in length, and apparently firm and solid. The indications at present are favorable for a complete restoration to health.

Speculations as to the future of this case are of little value, as it is impossible to say with any degree of certainty what may take place at the seat of the affection. It is possible that a stricture may develop, or new adhesions form followed by their characteristic symptoms. We all know the insidious nature of peritoneal bands and adhesions, that they may remain latent for a long time, and then without any apparent cause, develop a remarkable activity for mischief. Something of this kind may appear in this patient at almost any time, but the fact remains, that whatever the future may have in store for him, he has been rescued from a very dangerous condition by this operation, and possibly he may be again relieved by surgical measures should the occasion demand them.

Another point is worthy of notice in this connection and that is the following: If adhesions of the bowels to the abdominal walls can be destroyed mechanically, why may not those, which unite the coils of intestines with each other, or with the omentum? Extensive adhesions of the various pelvic and abdominal organs are frequently broken up in removing tumors from the peritoneal cavity, and with the exception of those involving the stump of a pedicle, or excised mesentery, they seldom re-form or give future trouble. A peritoneum which is recovering from a recent attack of inflammation is probably less susceptible to irritation, and hence bears operative procedures much better than it would in its normal state. The operation under these conditions may be looked upon as a secondary one, and hence freer from danger than a primary one would be. Should time prove these statements to be true, then it would seem reasonable to hope that benefit may be obtained by surgical measures in certain cases of peritoneal adhesions not amenable to other

methods of treatment. Observation and experience must determine the class of cases, if any there are, which may be relieved by operation. The extent of the attachments, their duration and strength, their location, the organs involved, the general condition of the patient, the urgency of the symptoms, are important points and require consideration. It would seem that in these days of antiseptics, when the peritoneum is no longer sacred to the eye or to the manipulations of the surgeon, the questions suggested above are worthy of further experimental observation.

## INJURIES OF THE SHOULDER.<sup>1</sup>

BY J. H. MCCOLLUM, M.D.

No attempt will be made in this paper to bring forward anything new in the treatment of injuries to the shoulder, but I have thought that it might be of interest to briefly report a few cases of dislocations which were under observation a much longer period than is usual, and in which the results were not as satisfactory as might be desired, and will also add three other cases of comparatively rare injury to the shoulder. These injuries are to be divided into fractures, dislocations, separation of the epiphyses and impairment of the function of the nerves supplying the part, particularly that of the circumflex. Contusions are only of importance from their liability to mask other and more serious injuries. The discussion of fractures about the shoulder-joint is beyond the scope of this paper. The remark is frequently made that a dislocation of the head of the humerus is a comparatively trivial injury, and that the result of the treatment is all that could be desired both by the patient and by the surgeon. Now while this is true in a certain proportion of cases, there are still many instances of properly-reduced and skillfully-treated luxations which are a source of annoyance to the surgeon and of trouble to the patient. It may be stated as a principle that the more muscular a patient the greater is the likelihood of trouble following the dislocation; the reverse may be said to be true of fractures. A word in regard to partial dislocations. When we take into account the shape of the glenoid cavity, the conformation of the head of the humerus, the powerful muscles which surround the joint and the laxity of the capsular ligament, it is extremely doubtful if these ever occur. How is it possible for the rounded head of the bone to remain upon the narrow rim of the glenoid cavity? It is true that the long head of the biceps may in some way prevent the head of the humerus from being thrown very far downwards or forwards, but if the head of the bone leaves the socket why should it not be called a complete dislocation? Concerning the subject of ancient dislocations so-called I have nothing to say; but the following account of the reduction of a luxation of four years standing, published in the "International Encyclopedia of Surgery," Volume 3, page 671, is unique and quite interesting. "Mr. B., a patient of Dr. Rice, a prominent physician of La Moille, Ill., met with an accident in November, 1877, by which he dislocated his shoulder. The patient, who was a farmer, failed, for some reason to obtain proper treatment, and applied after eighteen

<sup>1</sup> Read before the Boston Society for Medical Observation, November 1st, 1886.

months to Dr. Rice, who discovered the true nature of the injury and made patient efforts to reduce the luxation. After using as much force as he dared, this physician pronounced the case beyond cure and advised that no more hope be entertained of replacing the bone, as no nerves seemed pressed upon and as the arm was still measurably useful to the patient. In November, 1881, four years after the injury, the man was riding upon a horse and at the same time leading a blind horse behind him by a halter which he had carelessly wound about the hand of the arm dislocated four years before. While in this position the animal behind, becoming startled, suddenly jumped back, and Mr. B., who was unable to release his hand from the halter strap, was dragged forcibly backward, so that the traction was both backward and as he leaned further back somewhat upward. The shock of this sudden strain was so severe that the patient was taken to his house and placed in bed, it being believed by himself and others that he was seriously hurt. He slept for some hours, the pain not being severe, and upon awakening discovered that his arm was changed in some way. Further examination showed that the luxation had been reduced and the member soon recovered its mobility, and nearly its old strength."

In regard to the separation of the epiphyses it may be observed, that these injuries almost invariably do well if they are recognized. The local disturbance, however, is frequently so trivial that no physician is called, and the first thing noticed by the patient is a deformity, which, although comparatively slight, not only mars the symmetry, but also interferes to a certain extent with the motion of the joint. It is impossible in the greater proportion of cases, to make a correct diagnosis without ether.

CASE I. Miss A. B., forty-five years of age, while attempting to go down stairs lost her balance and endeavoring to save herself, seized one of the balusters with her right hand causing a dislocation of the humerus into the axilla. When the patient was seen, which was about one hour after the injury was received, she complained of pain near the joint, which was immovable and very sensitive to the touch. As the patient was very fleshy and as the bones were quite small, the deformity was very slight, so slight that a casual glance would not have detected any difference in the contour of the shoulders. There was no numbness of the fingers, and in fact, with the exception of the severe pain when any motion, passive or otherwise, was attempted, there was nothing that would indicate any severe injury of this joint. The patient was etherized, when it became evident by the application of the test of Dugas that there was dislocation of the head of the humerus into the axilla. The reduction was accomplished with very little difficulty. A pad was placed in the axilla and an immovable apparatus adjusted. There was considerable constitutional disturbance as is nearly always the case in these injuries. The apparatus was kept on the shoulder for two weeks, at the end of which time slight passive motion was commenced and continued at intervals of a day for three weeks. There was no difference in the appearance of the joints, but the motion was very much limited in the injured one. At the expiration of four years, the patient was unable to place the hand easily upon the top of the head, and in fact, has never fully recovered the use of the joint.

CASE II. J. T., a man fifty-eight years of age, was riding in a stage-wagon when the axle broke and the vehicle was overturned and the patient was at the bottom of a confused mass of humanity. The exact manner in which the accident was caused it is impossible to state. An eminent surgeon of New Hampshire was called, who administered chloroform, diagnosed a downward dislocation of the humerus which he easily reduced. The patient came under my observation twenty-four hours after he received the injury. When seen there was considerable swelling about the joint and very great constitutional disturbance. As the patient had travelled over one hundred miles the apparatus had become disarranged. Adhesive plaster, wedged-shape pad and bandages were applied, so as to render the joint immovable. Opium was administered and the patient placed in bed. At the end of two weeks the apparatus was removed and passive motion was used every day. There was no wasting of the deltoid. The man never fully recovered the use of his arm. Up to the period of his death, which occurred five years later, he was unable to raise his arm at more than a right angle to the body. Rotation of the humerus, however, was comparatively good. There was more or less neuralgic pain, however, as long as the patient lived. There was a slight prominence in the anterior portion of the joint, the cause of which has never been satisfactorily explained. Hamilton in his work on dislocations and fractures, speaks of this deformity as of very frequent occurrence after dislocations, and attributes it to the injury of the long head of the biceps; but as the long head of the biceps is comparatively rarely injured in dislocations it would seem as if this conclusion was erroneous. Other observers consider that it is due to the injury of the spinatus muscles and probable thickening of the capsule.

CASE III. A man, about forty years of age, was standing on a ladder about eight feet from the ground, when the foot of the ladder suddenly slipped and he was precipitated from this height, and put out his left arm to save himself, thereby causing an axillary dislocation. When seen, which was about three hours after the accident, there was a deformity characteristic of this dislocation. As the man was of a very spare habit, the diagnosis could be made at a glance. The patient was etherized, and the dislocation was easily reduced by means of placing the heel in the axilla. A pad was placed under the arm, which was firmly bandaged to the side. There was very little constitutional disturbance, and the subsequent swelling and inflammation of the joint were very slight.

The bandages were removed, and passive motion commenced at the end of two weeks. At the expiration of six months, although the motion of the joint was comparatively good, the man did not have free and perfect use of the arm. There was no change, however, in the appearance of the injured joint, as compared with the other. The limited amount of pain in this case is of interest when compared with the severe pain in the previous cases.

CASE IV. J. G., a man about fifty years of age, standing at the door of a saloon, was suddenly pushed down two steps, causing an axillary dislocation of the right humerus. It was impossible to discover just how he received this injury. When the patient was seen, he was somewhat under the influence of alcoholic stimulants. There was comparatively slight deformity,

but as there was great pain and tenderness about the joint, sufficient to render an examination without an anæsthetic impossible, he was etherized. A dislocation diagnosed and easily reduced. The usual apparatus was adjusted and kept in place for ten days. The patient stated that four years previous, he had received a similar injury to his arm. At the end of three weeks, at which time the patient passed from observation, there was comparatively good motion of the joint.

**CASE V.** A. B., while in a state of intoxication, fell on the sidewalk, and in some way dislocated his shoulder. When the patient came under observation, which was three days after the receipt of the injury, there was great swelling about the joint, so much as to mask the characteristic deformity, accompanied with very severe pain and marked constitutional disturbance. The man was etherized, and the dislocation reduced. Edema of the hand and numbness were present in a marked degree. At the end of a week the swelling was very much diminished, but, unfortunately, at this time the patient disappeared.

**CASE VI.** A woman, thirty years of age, was knocked down by the horses of a street-car, and received an injury of the right shoulder-joint. The patient was seen about an hour after the accident. There was loss of power, numbness of the hand, and severe pain in the shoulder. The deformity of the joint was not very marked, but on account of the pain, a satisfactory examination could not be made without an anæsthetic. The patient was placed under the influence of ether, and the diagnosis of a downward dislocation made. This was easily reduced, and the usual apparatus adjusted. At the end of two weeks passive motion was commenced. In this dislocation, as is frequently the case, there was wasting of the deltoid, and also marked inflammatory thickening of the capsule of the joint. At the end of six months the movement of the joint was much impaired, although there was very little pain. A slight prominence on the anterior aspect of the joint was very evident. The deltoid muscle was considerably smaller than the one on the opposite shoulder. At the end of a year there had been very little improvement either in the appearance or motion of the joint. At the end of four years the motion was not perfect, but it had improved slightly. The patient could now place the hand upon the vertex, but she was unable to place the upper part of the arm in contact with the side of the head. There was considerable loss of symmetry. For all usual avocations, however, this arm was nearly as useful as the other.

**CASE VII.** A. B., a man thirty-five years of age, fell on an icy sidewalk, and while trying to save himself by grasping the railing of a fence, caused a downward dislocation of the left humerus. The patient was seen about one hour after the accident. He was etherized, and the dislocation easily reduced. The usual apparatus was applied, and at the end of two weeks was removed. There was very little constitutional disturbance in this case, and the swelling and pain in the joint were comparatively trifling. At the end of four weeks there was a fair amount of motion in the joint, but there was very marked deformity on the anterior portion of the shoulder. Allusion has been made to this deformity in Cases II and VI. So great was this enlargement, that a superficial observer might mistake it for a dislocation. The head of the bone in this case

was certainly in the glenoid cavity, because the motion of the joint, although limited, was perfectly free and unembarrassed. The hand could be placed upon the opposite shoulder, and the inner elbow brought in contact with the thorax. A rule placed upon the arm projected about three-quarters of an inch from the acromion. At the end of three years the deformity had somewhat diminished, but the motion of the joint was still quite limited. Without multiplying cases, it has been shown, I think, that a dislocated shoulder-joint rarely, if ever, fully recovers its functions. It may be of interest, before finishing this subject, to allude to a remarkable result of a dislocation of the humerus, described by Baron Larrey in "Cooper's Surgical Dictionary," page 314: "Among the curious anatomical preparations (says he) which I saw in the cabinet of the University of Vienna, there was a dissected thorax, shown to me by Professor Prokaska, in which the whole orbicular mass of the head of the right humerus, engaged between the second and third true ribs, projected into the cavity of the chest. This singular displacement was the result of an accidental luxation, occasioned by a fall on the elbow, while the arm was extended and lifted from the side. The head of the humerus, after tearing the capsular ligament, had been violently driven into the hollow of the axilla, under the pectoral muscles, so as to separate the two corresponding ribs and pass between them. The diameter of the head of the bone surmounted this obstacle, and penetrated entirely into the cavity of the thorax, pushing before it the adjacent portion of the pleura. Every possible effort was made in vain to reduce this extraordinary dislocation. The urgent symptoms which arose were dissipated by bleeding, warm bathing, and anti-phlogistic remedies. The arm, however, remained at a distance from the side, to which condition the patient became gradually habituated, and after several years of suffering and oppression, he at length experienced no inconvenience.

"The patient was about sixteen or seventeen when he met with the accident, and he lived to the age of thirty-one, when he died of some disease which had no connection with the dislocation. His physicians were anxious to ascertain the nature of this curious case, of which they had been able to form only an imperfect judgment. They were much surprised to find, upon opening the body, the head of the humerus lodged in the chest, surrounded by the pleura, and its neck closely embraced by the two ribs above specified. They were still more astonished to find, instead of a hard, spherical body covered with cartilage, only a very soft, membranous ball, which yielded to the slightest pressure of the finger. The cartilage and osseous texture of the whole portion of the humerus, contained within the cavity of the chest, had entirely disappeared. Of the humerus, there only remained some membranous rudiments of its head, and a great part of these seemed to belong to the pleura costalis."

#### WASTING OF THE DELTOID.

**CASE I.** J. G., a man about forty years of age, fell on the sidewalk and injured his right shoulder. About three weeks after the injury he applied for treatment. At this time there was considerable pain on motion of the joint, and its movement was very much embarrassed. In order to prevent any possible error in diagnosis, the man was etherized, and a very careful examination was made. No fracture nor dislocation

could be detected. There was considerable diminution in the size of the deltoid muscle. A stimulating embrocation was advised, together with frequent champing of the joint. At the end of a week after the commencement of treatment, the thickness of the deltoid had diminished considerably. Electricity was now advised, in the form of the interrupted current. The man was under observation about eight weeks, at the end of which time the condition of the deltoid had not improved. There was complete paralysis of this muscle.

#### SEPARATION OF THE UPPER EPIPHYSIS.

This is spoken of by the authorities as a very rare accident, and were it not for the fact that a most careful examination had been made, I should be inclined to think that there had been an error in diagnosis.

CASE I. B. D., a boy, twelve years of age, was forcibly compressed between a high-board fence and the tail-board of a wagon, the wagon being brought in contact with his left shoulder. He was seen about one hour after he was injured, at which time there was a deformity in the anterior portion of the shoulder, just below the coracoid. When one hand was placed upon this projection, and rotation, with a slight upward pressure, made with the other, a peculiar, soft crepitus could be felt; when rotation was made outwards, this prominence moved slightly, but seemed to pass through the arc of a comparatively small circle. The forearm could be flexed and extended, both pronated and supinated without pain. Slight pressure downwards and backwards caused this deformity to disappear. There was comparatively little pain about the joint, so that a satisfactory examination was made without ether. An Ahl's shoulder-cap splint was moulded to the part, with a soft pad so adjusted as to bring firm, yet moderate pressure over the deformity. The arm was bandaged to the side. At the end of two weeks the splint was removed, in order to make an examination. Slight passive motion did not cause a recurrence of the deformity. The splint was re-adjusted, and at the end of ten days was removed. Slight passive motion was employed, the deformity did not return, and the patient had ultimately perfect use of the joint.

CASE II. A girl about six years of age, of a somewhat strumous diathesis, was forcibly thrown against the side of a house, and received an injury of the left shoulder. She was seen about an hour after the accident. There was slight swelling of the shoulder, and the characteristic deformity, to which allusion has been made in the preceding case, was observed. Owing to the slight amount of pain, an examination was possible without ether. Shoulder-cap splint was adjusted and kept in position three weeks. Passive motion was now used for a short time. The girl recovered perfect use of the joint, and there was no lack of symmetry in the shoulders.

My reasons for considering that the two preceding cases are examples of this injury, rather than fractures, are the peculiar appearance of the deformity, which is a distinct prominence just below the coracoid; a peculiar, soft crepitus (if I may be allowed the term), which is entirely different from the rough, grating feel, characteristic of a broken bone; the comparatively trivial pain, which rendered satisfactory examination of the joint possible without etherization; and the fact that at the end of three weeks, the union of the separated parts seemed to be perfectly firm.

### Reports of Societies.

#### BOSTON SOCIETY FOR MEDICAL OBSERVATION.

MEETING, November 1st, 1886. DR. A. N. BLODGETT in the chair.

DR. G. W. GAY read a paper upon

#### A CASE OF LAPAROTOMY FOR RECENT ADHESIONS OF THE INTESTINES TO THE ABDOMINAL PARIETES: RECOVERY.<sup>1</sup>

DR. RICHARDSON said that the paper was suggestive in bringing forward the question, What circumstances justify laparotomy? In some cases there can be no doubt, but in a large proportion the operation has to decide a doubtful point, and this is especially true of cases of obscure intestinal disease accompanied by obstruction. The severe cases of abscess about the vermiform appendix would be excluded from the list of doubtful cases. The speaker thought the practice of opening the abdomen to satisfy curiosity as to the disease and when nothing was to be gained further was altogether too common; he was sure that the success of over twenty laparotomies in his practice was such as to tempt him to perform the operation perhaps too freely. In the case reported, had the result been other than successful, it seemed to him the operation was justifiable when the percentage of mortality in similar cases left alone, was considered. While advising delay in operating in such cases of obstructive disease as did not present grave symptoms, yet one must be on his guard against delaying too long; in his own experience the delay of a few days in the case of a woman of seventy years, allowed her to become so exhausted that she died twelve hours after resection of the intestine, although the operation itself was perfectly successful, the joint holding both air and water.

DR. GAY said that the point on which he especially wished discussion was the one of most importance to the patients, that is, how much benefit is it to have peritoneal adhesions broken up. In cases of idiopathic peritonitis the patient may live for a long time suffering from adhesions, can he be cured by operating and breaking these bands? The question seems to turn upon the point as to whether these bands will re-form. It is known that they may not when only covering a comparatively small space. May not the same be true of very extensive ones? The limit of successful operations seemed to be between the two extremes of acute peritonitis, where the patient died of shock, and very severe cases where the patient was collapsed, and in the cold and sweating stage. He had operated in four cases when collapsed, but always with fatal result.

DR. BLODGETT asked the reader if the location of the intestinal adhesions in relation to their distance from the stomach would have any important bearing upon the result of treatment by operation? that is, if adhesions situated at a point upon the bowel nearer to the stomach would of necessity increase the perils of the patient either in the way of immediate shock during or after the operation, or would induce less favorable conditions during convalescence from the operation?

DR. GAY stated that the higher up the adhesions

<sup>1</sup> See page 25 of this number of the Journal.

are situated the more primary shock there is, and the greater liability of complications during convalescence.

An operation near the stomach is more dangerous than the same procedure nearer the cœcal end of the intestine.

Dr. RICHARDSON alluded to the manner of suturing the abdominal wound.

Dr. GAY said that in this case he had followed his usual method. He employed it from theoretical reasons at first, but always having had good success continued it.

Dr. FITZ inquired as to the ease with which the adhesions were broken down.

Dr. GAY said that there was but one spot that gave any trouble, although it was not always easy to find the dividing line between the adhesion and the bowel. He did not use the knife.

Dr. J. H. McCOLLOM read a paper upon

#### INJURIES OF THE SHOULDER.<sup>2</sup>

Dr. A. H. NICHOLS thought that the cases presented of uncomplicated shoulder dislocation, followed by long-continued after-effects, should be considered as rare exceptions; and that the surgeon would still be justified in predicting that the patient would regain the substantial use of the limb within a few months. The period intervening between the inception of the injury and the reduction, is an important element in considering the prognosis. Where this interval amounts to several days, the functions of the limb are less speedily resumed; possibly owing to the greater force necessary for accomplishing reduction under such circumstances. Hamilton mentions two years as the longest period of continuance of muscular ankylosis and weakness following a dislocation promptly reduced.

The paralysis and loss of symmetry, or atrophy of the muscles, particularly of the deltoid, cannot always be referred to the effects of muscular contusion or rupture; for these same phenomena have been observed when the arm has been subjected to violent extension only, where there existed no suspicion of dislocation or muscular injury. Such symptoms would seem to be most satisfactorily explained upon the theory of rupture of the circumflex nerve.

Dr. GAY said, one important point is suggested by Dr. McCollom's paper, and that is the question of a permanent injury. Every medical expert is pretty certain to be asked this question: "In your opinion, Doctor, will the patient ever have as good an arm, as before the accident?" In other words, is the injury a permanent one? The cases reported here would indicate that the question cannot be answered by either a yes or a no. It should be qualified somewhat as follows: The arm, which has been dislocated at the shoulder, will probably never be quite as free in its movements in certain directions as it was before the accident, but for most of the ordinary uses of the arm it will be as good as ever it was. While the effects of the injury may never wholly disappear, yet it is by no means permanent, in the sense of total or even partial disability to fulfil all the ordinary functions which may be required.

Another feature of these cases is, that improvement continues to manifest itself for a long time after the ordinary convalescence. This is particularly true of joints. At the end of six months, or even a year, the patient may experience a good deal of trouble in con-

sequence of the injury, but that is no good evidence that they will never recover. Chronic joint affections oftentimes require years for a complete, or even a fair recovery. Hence it behooves the expert to be slow in pronouncing any doubtful case of injury to joints a permanent one, in the sense of permanent impairment of the ordinary functions of the limb.

Dr. McCOLLOM said that one of the patients, seen six years ago, was still unable to put the hand to the head. The case was interesting because at the time it was a legal matter and the question of how much disability was simulated arose. The case having been long settled, that element was removed.

Dr. BLODGETT remarked that he had hoped to hear some allusion by the reader to a condition of the shoulder which has at times presented itself in his practice. He alluded to the habitual and recurrent dislocation of the shoulder after a primary injury of greater or less severity, by which the head of the bone was in the first instance dislocated into the axilla.

One such case has been seen by Dr. Blodgett, in which a primary dislocation of the shoulder fully recovered as far as the ordinary treatment of such cases is concerned, but in which any unusual exertion or incautious movement is liable to be followed by an immediate and complete displacement of the head of the humerus into the axilla. The patient was so accustomed to this accident, that he was not alarmed by its occurrence, but sought surgical aid, giving directions how the dislocation was to be reduced; and on the accomplishment of the reduction the patient quietly put on his coat and departed, to be seen no more until a recurrence of the dislocation made it necessary that he should again seek surgical aid. The very trifling amount of disturbance caused by the dislocation of so important a joint as that of the shoulder may well excite surprise, and the comparatively little disability following this injury in most cases is remarkable.

Dr. E. O. OTIS stated he had a patient in whom the accident had occurred several times.

Dr. STRONG said that he had had under his care a woman of about seventy years who could at will produce complete downward dislocation of the shoulder but could not get it back without medical aid. He had reduced it four times.

Dr. MARION had reduced one shoulder three times, and knew that others than himself had reduced it. He inquired as to the necessity of placing a pad in the axilla.

Dr. McCOLLOM said the pad made the patient more comfortable and certainly diminished the chances of the head of the humerus slipping out.

---

— Prof. F. S. Dennis, of New York, while crossing the Atlantic, made some experiments for testing the purity of air one thousand miles from land, in the line of those by Tyndall upon the mountain air of Switzerland. In one capsule of sterilized gelatine exposed in the state room upon the main deck of the steamer, within eighteen hours over five hundred points of infection had developed. Two capsules exposed in a similar manner in the cabin on the promenade deck, where the circulation of air was free, showed five or six points each ten days afterwards. A capsule exposed over the bow was entirely uncontaminated.

## NEW YORK COUNTY MEDICAL ASSOCIATION.

STATED meeting, December 20th, 1886.

DR. FRANK GRAUER read a paper on

## THE PATHOLOGICAL ANATOMY OF SCARLATINAL NEPHRITIS.

Although a great deal had been done within the past ten years in the pathology of scarlatinal nephritis, he said, there still existed differences of opinion as to the minute changes which occur in the various forms of the trouble. Friedländer had classified the different forms met with post-mortem, under three types, namely, initial catarrhal nephritis; large, flabby, hemorrhagic kidney; and acute glomerulo-nephritis, or nephritis post-scarlatina.

The initial catarrhal nephritis was the form that we met with in the first week of the disease; generally accompanying the exanthema, lasting from a few days to a week, and then gradually disappearing. It rarely led to death, and was only recognized by a chemical examination of the urine; in which were to be found a slight amount of albumen and mucus and hyaline casts—more rarely red and white blood-corpuscles, renal epithelium, and granular casts. The symptoms very rarely pointed to kidney trouble, and if any such were present, they were liable to be overlooked.

In this affection the kidneys were slightly enlarged and hyperæmic, the capsule stripped off very readily, and in a cut-surface there was some thickening of the cortical substance, with more or less loss of striae, while the glomeruli appeared as red dots. Microscopical examination showed swelling and granular degeneration, with desquamation of the epithelium, especially that lining the convoluted tubules. Hyaline and granular casts were often found in the straight tubes, and, where the process had been more severe, the beginning of a round cell infiltration in the interstitial tissue. It was only in those cases in which children died from the sequelæ or complications of scarlatina, such as diphtheritis and broncho-pneumonia, that we were able to notice the changes referred to. It might be supposed that these changes were indications of a parenchymatous inflammation, but Friedländer had pointed out the following differences: parenchymatous inflammation, according to Virchow, leads to fatty degeneration of a cell, with disturbance of its function; and this process does not occur in the epithelial cells lining the uriniferous tubules in the affection in question. Then, on the other hand, we have a cellular proliferation in initial catarrhal nephritis which does not, as a rule, occur in parenchymatous inflammation of the kidney.

The second form of nephritis, characterized by large, flabby, hemorrhagic kidney, was not as common as either of the other two forms, and was met with in only twelve out of two hundred and twenty-nine cases in which Friedländer made autopsies. It generally occurred from the first to the fourth week of the disease, and ran a rapid course. In some cases the urine was normal up to within twenty-four or forty-eight hours of death, and œdema rarely occurred. This form of nephritis was generally found in those cases accompanied by extensive angina and diphtheritic inflammation.

The kidneys were found to be enlarged and softened, and the cortical substance was thickened, and greyish-red in color. There was complete loss of the striae,

and the glomeruli, as a rule, were invisible. The cortex was studded with ecchymoses and large hemorrhagic infiltrations. Microscopically, the tubules were seen to contain the various forms of casts, red blood-corpuscles, degenerated and desquamated epithelium, and an increase in the connective tissue characterized by a round cell infiltration situated mainly around the glomeruli and between the convoluted tubules. Besides the above changes, small abscesses were often found in the cortical substance, in which, by means of one of the aniline dyes, it was not infrequently possible to detect micrococci. Whether these microbes had any distinct relation with the etiology of scarlatina or diphtheritis, or whether they were merely one of the forms of micrococci commonly found in acute abscesses, Dr. Grauer was not able to state. This form of nephritis was not characteristic of scarlatina, as it had been found in some forms of primary diphtheritis; and Friedländer regarded it as a septic inflammation of the kidney.

The third variety, acute glomerulo-nephritis, was almost characteristic of scarlatina, and rarely occurred in other diseases. Dr. Grauer had met with it once, however, in a case of heart trouble. It generally occurred in the third or fourth week of the disease, when the patient was convalescing. Usually without other symptoms, œdema was noticed about the eyes and lower extremities, and an examination of the urine showed evidences of albuminuria. The urine was also turbid, diminished in quantity, and of a high specific gravity.

Microscopical examination showed hyaline casts, renal epithelium, red blood-corpuscles, and, occasionally, epithelial and blood casts. While in some cases recovery promptly took place, in others the process was progressively unfavorable. The œdema increased, fluid accumulated in the peritoneal, pleural and pericardial cavities, the urine kept on diminishing and became bloody, and the albuminuria became more marked. Microscopic examination now showed it to contain a large number of red blood-corpuscles, pus and renal epithelial cells, and hyaline, blood, granular and epithelial casts. Then came uræmic symptoms, with anuria and death. Friedländer found this form of nephritis in forty-two out of the two hundred and twenty-nine cases that he examined.

Klebs was the first to point out that the glomeruli were affected in scarlatinal nephritis. On making fresh sections of the kidney with a double knife, he found that the glomeruli were anæmic, and on washing out the same in water they became dark and cloudy. Microscopically he noticed small irregular nuclei imbedded in a granular mass, and within the capsule proliferation of the capsular epithelium; while the capillaries were almost completely covered by a mass of nuclei. On tearing apart the glomeruli with needles he found the glomerulo-epithelial cells more adherent than normal, and varying in shape. Occasionally some of the cells were found to be fatty. Situated between the glomerulo-epithelial cells and the walls of the capillaries were small irregular nuclei, and from their shape and appearance he came to the conclusion that they were nuclei of the proliferated connective tissue cells, and that they produced a compression of the capillaries, which caused the diminution and suppression of the urine. In this Dr. Grauer thought he was probably mistaken, as there was no evidence of connective tissue situated between the

glomerulo-epithelium and the walls of the capillaries in a normal kidney.

Having devoted some time to the discussion of the microscopical anatomy of the glomeruli, in regard to which he said there still existed some differences of opinion among histologists, he stated that Klein, in twenty-five autopsies of those who had died of scarlet fever, observed the following changes: increase of nuclei, probably covering the glomeruli, and hyaline degeneration of the elastic intima of the minute arteries, especially the afferent arterioles. The intima of these vessels in places appeared swollen up into cylindrical or spindle-shaped hyaline masses, which produced a distinct narrowing of the lumen of the vessels. In connection with this he observed a similar hyaline degeneration of the capillaries of the Malpighian corpuscles in the course of which greater or smaller parts of the glomeruli became obliterated. The degenerated parts were at first hyaline, and later on assumed a more fibrinous aspect; Bowman's capsule at the same time becoming thickened. A third change that he observed was multiplication of the nuclei of the muscular coats of minute arteries and a corresponding increase in thickness in the walls of these vessels. The changes in the glandular part of the kidney he thought were indications of a parenchymatous nephritis, and he did not think that the anuria and uræmic poisoning were due to compression of the vessels of the glomeruli, but to the changed state of the arteries.

Having referred to the observations of Ribbert and Langham, he went on to describe his own researches, based upon nine cases of glomerulo-nephritis that occurred at the *Algemein Städtisches Krankenhaus* in Berlin, and conducted at the pathological laboratory of Dr. Carl Friedländer. He gave the results of the post-mortem examination in each case, and then went on to say that in glomerulo-nephritis, the kidneys were enlarged and hyperemic. There was no loss of cortical striae, and in some cases the cortex might be somewhat thickened. The glomeruli were pale, prominent, and more or less enlarged.

As regards the microscopical examination, the uriferous tubules were apparently normal. There might be some evidence of a slight parenchymatous inflammation, and the epithelium might be somewhat swollen, while occasionally a cast in the tubules could be seen. The glomeruli were bloodless. Very rarely, a red blood-corpuscle could be found in the lumen of a capillary. When examined with a low power, the glomeruli were found larger than normal, and covered with a mass of nuclei. With an immersion-lens, the following changes could be noticed in the capillaries: In some, the only change was a thickening of the endothelial layer, which became more granular. In others, the lumen of the vessel was filled with a rich, nuclear protoplasm. Dr. Grauer's opinion was that these nuclei were the nuclei of proliferated endothelial cells, rather than the nuclei of white blood-corpuscles, as held by some authorities. They were, he claimed, smaller and darker than the latter; and he had also seen an endothelial cell swollen and projecting into the lumen of the capillary, and completely obliterating its calibre.

With reference to the glomerulo-epithelium, he had noticed swelling and proliferation. It was still considered by some that it was the proliferation of the glomerulo-epithelium that produced a compression of

the capillaries, and thereby obstructed the circulation; but in all the specimens examined by Dr. Grauer, although proliferation was present, the loops, as a rule, were larger than normal, showing that the pressure was from within, and not from without. Proliferation of the capsular epithelium, as described by Klebs, was not observed in eighty-two sections that he examined, although he had noticed it in other forms of scarlatinal nephritis.

Hypertrophy of the left ventricle of the heart was always present in cases of glomerulo-nephritis, as first pointed out by Friedländer, and it was due to the heart's being compelled to do more work, on account of the obstruction in the Malpighian tufts. In conclusion, he expressed the opinion that the term glomerulo-nephritis ought to be limited to those affections in which there is an obliteration of the loops of the capillaries, and not applied to those in which there is only a proliferation and desquamation of the glomerulo- and capsular epithelium, as this change has been noticed in all forms of chronic nephritis. After reading his paper, Dr. Grauer exhibited, under the microscope, a number of specimens illustrating some of the points referred to in it.

DR. A. FLINT remarked that Dr. Grauer was worthy of much commendation for the careful manner in which he had studied this subject. Our knowledge of glomerulo-nephritis was of comparatively recent origin, and was chiefly due to the improved microscopes and improved methods of staining now at the command of the investigator. He had lately been much impressed with the immense advantages of the modern lenses over the most perfect ones formerly in use while making some examinations of tubercle bacilli.

One of the questions of interest which was suggested by the paper was that relating to death from so-called uræmic poisoning. This was a live question, and, personally, he had very decided convictions in regard to it, which were considerably at variance with the views which he had formerly held. From the investigations which he had made during the last few years concerning excrementitious substances, he now entertained doubts as to whether urea was, after all, a poison. His experiments had convinced him that water was formed *de novo* in the system from a combination of the elements composing it, so that, under these circumstances, water itself was an excrementitious product, and yet it was certainly not a toxic agent. As to the cause of death in these cases of scarlatinal nephritis, which were commonly attributed to uræmic poisoning, he believed that the parenchymatous changes which were noted in the patient after death were due very largely to the excessive pyrexia of the scarlet fever. The special direction which these parenchymatous degenerations took in different infectious fevers were governed, he thought, by the special cause of the disease, each affection having its own peculiar *contagium vivum*, with its specific mode of action in the system. In scarlatina, there was a strong tendency for trouble to locate in the kidneys, and in scarlatinal nephritis, the urine was diminished in quantity and concentrated, and contained a large amount of albumen, because these organs became choked with excrementitious matter, and could no longer be washed out by the water derived from the Malpighian tufts.

DR. ISAAC E. TAYLOR said that in the cases to which Dr. Grauer had devoted special attention, death had occurred in from four to eight weeks. He should

like to inquire what would be the condition of the kidneys in those cases which terminated fatally within thirty-six hours from the onset of the attack of scarlatina. In this connection, he related several cases which had occurred in his own experience.

DR. L. J. McNAMARA said that if there was swelling of the endothelial cells, filling up the calibre of the tubules, as described by Dr. Grauer, it would overthrow the theory formerly entertained, that these tufts of capillaries are composed of nothing but epithelial cells without nuclei. Or, possibly, the condition might be explained on the hypothesis of the existence of two sets of cells, one variety being nucleated, and the other not.

DR. DANIEL BROWN thought that the virus of scarlatina found a soil peculiarly fitted to it in the skin, the intestines, and the lining membrane of the glands, and that, by its effect upon these structures, an irritation of the nervous system was set up that was sufficient to account for the class of cases referred to by Dr. Taylor. It was very much as though the child died from shock. Scarlet fever had the effect of arresting almost all the secretions of the body, and, therefore, in his treatment he was in the habit of employing such remedies as tend to stimulate the secretions. By pursuing this course, he had found that the temperature was kept down, and that the danger of unpleasant sequelae was greatly diminished.

DR. J. W. S. GOULEY said that a number of years ago, during several epidemics of scarlatina at the Nursery and Child's Hospital, it had been somewhat surprising to him, as well as to Dr. Elliott, who was one of the attending physicians, that so many of the children were affected with nephritis; and the point that interested him most was, that of the many who recovered, the larger number recovered promptly and completely. He should like to inquire, therefore, whether it was not rare for chronic nephritis to result.

The President, DR. LEALE, said that some fifteen years ago, when he was attending physician for diseases of children at one of the largest dispensaries of the city, he was struck by the large number of cases of dropsy that presented themselves; and he found that the great majority of these were in children who had passed through an attack of scarlet fever without any medical attendance. An interesting point that he had noticed in examining the urine from day to day in cases of scarlatina was that, although for a time there might be no sign of kidney trouble, it was a fact that albumen appeared in it almost invariably on the twenty-first day. It thus followed close upon the desquamation of the skin. When scarlatinal dropsy was moderate in amount, there was usually little difficulty in promptly relieving the patient.

DR. GRAUER said that in the cases referred to by Dr. Taylor, in which death occurred within twenty-four or forty-eight hours, there was complete suppression of urine, and that the condition found after death was acute glomerulo-nephritis. In reply to Dr. Gouley's question he stated that while in the majority of cases the children undoubtedly recovered promptly, in a certain proportion of cases the kidney trouble became chronic. He had at present, under observation, a child of eight years, who had an attack of scarlet fever two years ago, and who now, as a result was suffering from chronic interstitial nephritis, with bloody urine.

#### PERFORATION OF THE APPENDIX VERMIFORMIS: LAPAROTOMY.

DR. JOSEPH D. BRYANT presented a vermiform appendix which he said he had removed from a patient last summer. The case occurred in a neighboring town, and was seen in consultation with Drs. Janeway and W. T. Bull. The cause of the illness, which occurred in a gentleman, forty-five years of age, previously in good health, was entirely unknown.

Almost fifty hours before Dr. Bryant saw him he was suddenly attacked, without appreciable cause, with a moderately severe pain in the epigastrium region. He attached but little importance to it, and, attributing it to a mild diarrhoea, from which he had been suffering for ten or twelve hours previously, took a gentle cathartic, which afforded him marked relief. He noticed no pain or tenderness in the right iliac region.

About fifteen hours afterward the pain became more severe than at the outset; but was still located in the epigastrium. The family physician was now called in and he prescribed another cathartic, followed by an anodyne. The medicine did not move the bowels, and the pain increased; while the abdomen now became tympanitic, and nausea, with occasional vomiting, set in. The vomiting, however, was not characteristic of any special morbid process. Enemata were administered, but served to dislodge only a few small scybulous masses.

The condition of the patient became gradually worse, and Dr. Janeway was called in consultation; arriving about forty-five hours from the first attack of pain. Five hours later he was seen by Drs. Bryant and Bull, and the following facts were noted: The patient's perceptions were intact, although somewhat blunted by the previous use of opium. Persistent, though not severe, nausea existed, with occasional vomiting. The vomited matter had no distinctive characteristics. The abdominal walls were extremely distended, with tympanitic resonance well marked in all situations. Hepatic dulness normal. Tenderness on pressure was general, but best marked at the lower portions of the abdomen. No isolated point of special tenderness was discovered, and all pain was still referred to the epigastric region. The abdominal walls were too tense to render deep palpation of any service as a diagnostic measure, and digital rectal examination disclosed nothing abnormal. Temperature 102°, pulse 108. Respiration increased in frequency, but painless. Bowels obstinately constipated, with an absence of all intestinal sounds, and of appreciable vermicular movements. The thighs were flexed. Urine drawn off with a catheter.

As the result of this examination the consultants believed, (1) that a more or less general peritonitis existed; (2) that it was secondary to either obstruction of the intestinal tract or perforation of it; (3) that immediate measures of relief must be taken to insure a chance for recovery; (4) that medicinal measures afforded no such chance; (5) that an exploratory incision of the abdomen was warranted.

The patient having willingly given his consent, the operation was performed in as thoroughly an antiseptic manner as the contingencies of the case would admit. As soon as the peritoneum was incised a very small amount of thin, non-offensive, reddish-colored fluid escaped. The small intestines were extremely distended, and their serous surfaces were deeply cou-

gested. The sigmoid flexure (which extended across to the right iliac fossa) presented similar appearances. In some situations evidences of recent lymph were seen. No characteristic local indications of an obstruction could be found anywhere. The intestines at and about the right iliac fossa presented the evidences of a more profoundly inflamed condition, and for this reason the caput coli was closely examined. It, too, presented appearances similar to the contiguous intestines.

The vermiform appendix was then sought for and found, but with considerable difficulty. It arose from the inner and peritoneal surface of the cecum, was about two and one-half inches in length, was covered entirely by peritoneum, and was unattached, except at its origin from the cecum. It was standing nearly erect between the intestinal folds. It was swollen and darkly congested, and presented somewhat the outline of a distended leech. At its base three perforations were found; two of which were each about the size of a small pea, while the other was of somewhat smaller size. In one of the openings was a small mass of fecal matter. At and around the base of the appendix a considerable amount of the reddish non-offensive fluid mentioned was found, and it was mixed with flakes of recent lymph.

The appendix was tied at its base, below the points of perforation, with a strong silk ligature, and removed with scissors. The abdominal toilet was performed with antiseptic sponges, and a warm solution of bichloride of mercury ( $\frac{1}{1000}$ ). A drainage-tube was introduced, and the abdominal wound closed and dressed antiseptically. The patient rallied from the immediate effects of the operation, but died twelve hours afterwards from exhaustion.

In concluding his report Dr. Bryant called attention to the following special points of interest in connection with the case: (1) The preceding diarrhoea; (2) the absence of distinctive pain at the seat of the lesion; (3) the location of this pain in the epigastric region; (4) the comparative quiet following the first attack; (5) the existence of normal hepatic dulness; (6) the extension of the sigmoid flexure to the right iliac fossa; (7) the unusual arrangement of the vermiform appendix; (8) the absence of the evidences of any restricting inflammatory process; (9) the uncertainty attending the diagnosis of the existing cause of the patient's condition; (10) the unusual means adopted for the relief of the patient.

#### TRANSACTIONS OF THE CHICAGO GYNÆCOLOGICAL SOCIETY.<sup>1</sup>

##### DISCUSSION OF DR. JAGGARD'S PAPER ON REDUCTION OF INVERTED UTERUS BY COLPUREYSIS.

DR. PHILIP ADOLPHUS. The author of this excellent paper has adopted in the reposition of the uterus of his patient, as efficient a mode of procedure as any hitherto in use. It is also the safest mode of replacing the organ. In the treatment of chronic inversions, success has followed all methods of replacement, whether effected gradually or rapidly. But forcible taxis ought to be the last resource, when gentler and as efficient means are exhausted. It may lead to laceration of the vagina, peritonitis and death.

<sup>1</sup> Concluded from page 17.

Gradual pressure, sustained or interrupted, solid or elastic, to which taxis has been added, has been equally successful, and has been practiced since 1858. It is absolutely safe. In some cases air pessaries or other elastic contrivances have been left in the vagina constantly, or have been replaced at intervals, for a period of three to eighteen days, and *uteri* have been returned by this method, which were inverted from one to fifteen years. The essential to success in the return of an inverted uterus is patient, gently continued manipulation of *some portion of the uterus*, by the fingers in the vagina with the application of the other hand externally to overcome the constriction of the cervix, and to prevent the forcible elongation of the vagina. A small hand, which observes the course of the pelvic axis, and avoids the promontory of the sacrum, and goes on one side of it, is also an element of success. Old adhesions opposing reduction of the inverted uterus are rarely present. An inflammation of the serous tissue in some portion of the pelvis may however be present as a complication, for this is an extremely common affection in all kinds of pelvic disease. Doubtless, in cases in which peritonitis followed manipulations, a chronic or subacute inflammation of the serous tissues was the predisposing cause. However, the most interesting portion of this subject to me is that of diagnosis, *in all tumors lying in the vagina*, which do not pathologically implicate that organ and the vulva. A correct diagnosis in inversion of the uterus is absolutely essential to treatment and the safety of the patient. The question of differential diagnosis between inversion of the uterus and polyp and fibroids is almost daily presented to the gynæcologist for solution. Not much reliance can be placed on the history in *chronic* inversion, for the diseases present similar symptoms. The size of inverted uterus of some standing is scarcely larger, and is often smaller than in the natural state. It is desirable to look on the case under examination as one of inversion as long as any doubt exists. The bowels and the bladder should be emptied and the patient examined under ether. It is certainly *not* a case of inversion, when by bimanual palpation, with fingers in the vagina, fingers or hand into the rectum, or sound in the bladder, the *unimpaird roundness* of the uterus presents itself for palpation, either in the normal or retroverted position. In the just mentioned condition, if the sound enters the uterus two and a half inches or more, the uterus merely contains a fibroid or polypus which emerges from the cervix. The diagnosis may be rendered more difficult if no opening in the *cervix uteri* can be found, the cavity having been agglutinated by previous inflammation, to the polypus. Here downward traction of the vaginal tumor to the vulva, by a vulsellum as recommended by Susdorff, and I copy his words, will at once confirm the presence of a polypus. "For the relations of the parts to each other as they existed in the vagina will be greatly changed when exposed to view. The lips of the cervix which surrounded the pedicle will have disappeared, having also become inverted, and along with it, probably, the vagina at its junction with the neck." The insinuation of the sound into the uterus will at once confirm the information procured by bimanual palpation. If the same manner of examination discloses the body of the uterus indented or cupped, we have a partial inversion, either with or without a fibroid, a condition which is not as unfrequent as is generally supposed. The

presence of a tumor in the vagina, the absence of the *fundus uteri* in the abdomen, and the presence in its place of a well-defined ring or cup-shaped cavity, unmistakably announces an inversion of the uterus; traction confirms the diagnosis. An incision, not a puncture, along the sides of the tumor, after the patient emerges from the ether, will at once show whether we have to deal with the *fundus* of the organ or a polypus. In the one case it will induce pain, in the other it will prove painless. In the former it will relieve the congestion and possibly lead at once to its reposition, or prepare for its successful replacement in the future.

DR. H. P. MERRIMAN. I would like to ask whether, after the uterus had been partially restored so that the *fundus* was on a level with the lips, and the colpeurynter seemed to do no good for eight days following, taxis would not probably have promptly, almost immediately, accomplished the remaining portion of the work.

DR. H. T. BYFORD. Every method has danger, and there was one danger in this method which should be mentioned, that is the danger of sepsis or resorption of decomposing secretions. That there was danger even in this admirably managed case was evidenced by the rise in temperature, followed by the disappearance or decline in temperature on cleansing the bag and vagina. I have seen the immediate decline of fever by washing out the uterus when enlarged and filled with decomposing matter. I object to the introduction of the hand into the rectum to diagnosticate a case of inversion, as suggested by Dr. Adolphus. I consider it a dangerous practice because it does a violence to the part which sometimes has done an irreparable injury, and is unnecessary.

DR. W. H. BYFORD. With reference to the subject of inversion and more particularly the diagnosis, there are two points which I think are very important in addition to those mentioned by Dr. Jaggard. In cases of polypus attached to the neck of the uterus and filling up a good part of the vagina, I think the uterus is always enlarged and may be palpated above the pubes. Another point in the diagnosis is the difference in the sensation imparted to the examining finger. A polypus feels as if covered by a shining, smooth membrane, unless it is decomposed, while the surface of the uterus gives the sensation of pushing the finger into plush or velvet. I give these two points of diagnosis as the results of my own observation and as being usually present. With reference to the mode of reducing inversion, I will give some of my own experiences during the last thirty years. In the year of 1859-60, I had a patient sent to me from Lafayette, Ind., with a chronic inversion of the uterus, which I attempted to reduce. I had just read a long treatise on the subject by Dr. White, of Buffalo, and Drs. Thomas and Emmet were then beginning to talk and write about these things, and I went at it with considerable enthusiasm. I got up the cup that Dr. Jaggard mentioned, and I also got a large rectal bougie, an instrument which Dr. White had praised very highly in his first operations, and I made the first attempt, lasting about an hour and three-quarters, and when I got through I was worse off than the patient, although she was pretty badly used up. I waited two or three weeks and made another attempt, but after a protracted effort I found my finger passing through the *fundus uteri*. I had been as cautious about the force as I

could be, making the effort as gradually as possible, but I perforated the *fundus*. I fully expected that the damage done would be fatal to the patient, but it did not produce any bad effect whatever, and she entirely recovered in two weeks and went home. Two years later she came to see me again but did not wish to have another effort made to have the uterus reduced. Two years later the uterus was found in its normal position. I saw the patient and her physician and I am certain that nothing had been done to reduce it. I tried two other cases, and made the same efforts but without success. I then concluded that it was hardly worth while to make trials of that nature again, and in the next case I tried the colpeurynter treatment. For some days I was nonplussed, from want of experience, as to the mode of placing the instrument in the vagina. I used the quadrilateral colpeurynter, and after I placed it in the vagina, I found the next day that I had gotten it under the uterus lengthwise, that the *fundus* was directed toward the vulva, and the neck directly backwards. I was merely compressing the body of the uterus against the symphysis pubis. I reflected considerably before I could get the right idea as to the manner of placing the instrument in the vagina. Finally I pushed back the *fundus* until the axis of the uterus corresponded to the axis of the superior strait and then introduced the colpeurynter as has been described by Dr. Jaggard, and applied the force.

The next day when I came back I found there had been some impression produced, and I went on with the use of it taking it out every day and replacing it in this manner until in seven and a half days the inversion was reduced. The patient was a poor woman and it was necessary for her to take care of her child. She did so, attended to it in every way, and also cooked three meals a day for her husband. She was on her feet nearly the whole daytime, and yet the instrument acted as well as if she had been lying in bed. Three out of the five cases I have operated on have been as painless as this. I should judge that a young primipara would probably suffer more from the use of the colpeurynter than one who had had children. I have now reduced five cases of inversion by the colpeurynter and have not failed in any case since I commenced using the instrument. The first case of inversion I had I amputated the uterus. And in considering the matter since I doubt if any other treatment could have been adopted, which would have been effectual. The uterus and vagina were both inverted, the whole vaginal canal was entirely outside of the body and the uterus hung down from it, both making a tumor nine inches long. The uterus was very much enlarged in consequence of its being dependent for so long a time. I was in consultation with two German physicians of this city and they suggested as the patient was living a miserable life, and would die before long, we should cut it off. After half an hour's use of the *écraseur*, it was removed. We amputated a little below the centre of the cervix. There was no bleeding, nothing to give rise to uneasiness. We pushed the vagina back again, put the parts in place and the patient recovered in the course of a month. Having spoken of one spontaneous cure, I will tell you of a patient that I attended in Mercy Hospital, in 1864-65, whose uterus was much in the same way as the one that I first operated on, coming out entirely beyond the vulva and dragging down the vagina very low so that there was

simply a circular sulcus between the labia and the vaginal wall. I tried to restore it by manipulation and failed; I proposed to amputate it but the patient would not consent. Meantime one of the internes had fallen in love with her and they went off to Missouri and got married. About six years afterwards, the doctor came back and told me that he had a son and his name was Byford. Upon inquiry I found that the child had been borne by this woman. One case of inversion occurred in my own practice. I attended the patient during confinement, and so far as I know she had no difficulties whatever for seven or eight days. By that time I was on my road to California, and I think Dr. Roler looked after her for some little time after I was gone. In two months I returned home and was informed that she had inversion of the uterus, which I did not believe. I went to see her and found that she was suffering from complete inversion. That was one of the cases I cured by colpeurysis. When the inversion occurred I do not know. I am certain that I made two or three examinations, as I always did at that time, always one the second day after confinement. I did not notice anything of the kind, and yet it might have been commenced and finished afterwards. I saw a case with Dr. Henry Byford which had been attended by a midwife in which the inversion occurred so that the fundus could be touched through the mouth of the uterus, and it remained in that way two or three weeks. The patient was bleeding, but I believed the contraction of the mouth of the uterus was sufficient to prevent it coming through; I advised ergot, and in a few days the uterus was in its proper position.

DR. EDWARD WARREN SAWYER. One point in the persistence that one can observe in applying the colpeurysis, without a fatal result following. The interesting case that Dr. Byford has spoken of last also shows the possibility of the obstetrician seeing nothing in the first few days of the puerperal state to suggest that anything has gone wrong. Cases are recorded in which the inversion has taken place without the obstetrician knowing it. In the fatal case that occurred in my practice the symptoms were so profound that it was impossible to overlook it, and I think the diagnosis of recent puerperal inversion of the uterus is much easier than of chronic inversion. In the case which occurred in my practice, the rim of the crater marking the upper border of the uterus, which I palpated through the abdomen, was fully as large as a common bowl, and its edges were very sharply defined. In addition to that the fundus could be distinctly felt through the os uteri. One feature of the paper which is by no means the least to be commended is the very admirable and graphic way in which the case was presented.

DR. H. F. NEWMAN. My experience has been limited, but I remember a single case, in which I assisted a surgeon of this city in attempting the reduction of a chronic inversion of the uterus. It was in a hospital, where they had every facility for the operation and it could be proceeded with leisurely. Some two hours were taken up with the various devices for reducing the inverted fundus, all of which were of no avail. There was a complete inversion of the uterus but not of the vagina, and I think previous to the attempt at reduction a fibroid was removed from the fundus of the uterus. No further myomatous condition was discovered at the time, but the difficulty was exceedingly

great in this case and nothing whatever was accomplished. I have no knowledge of the subsequent condition of the patient, whether she suffered materially from this, or whether she was afterwards successfully operated on, or the uterus amputated.

The PRESIDENT asked Dr. Jaggard what means he used to disinfect the colpeurynter.

DR. JAGGARD replied that he washed it thoroughly with soap and warm water, afterwards disinfecting it with a five per cent. solution of carbolic acid. The vagina was irrigated with a two per cent. solution of carbolic acid, and a bacillus of iodoform introduced.

DR. ADOLPHUS in reply to Dr. Henry T. Byford. In complicated cases of tumor in the abdomen or pelvis I would not do without the introduction of the hand into the rectum. I am not alluding to Simon's method, putting the hand in as far as the elbow, but I am talking of the hand. And when the patient is under ether, it can be done easily. It depends upon the size of the hand, perhaps, but with a hand well greased and introduced slowly it does a great deal of good and gives an immense deal of information which we cannot get in any other way. I examine every case, without exception, *per rectum*, with the finger.

The PRESIDENT asked Dr. W. H. Byford if he regarded it good practice after all ordinary means had been exhausted and the uterus was still inverted, to amputate?

DR. W. H. BYFORD. When all other measures have failed to effect the object and the patient is suffering so much as to make relief imperative, yes.

The PRESIDENT. I saw Professor Chiara, in Florence, operate upon a case of that sort. He placed a silver wire around the uterus and left it in position, and the parts gradually sloughed away.

DR. W. H. BYFORD thought that mode of operating upon the uterus bad, that it would have been better to have used the wire écraseur to stop circulation, and cut it off. But a sloughing mass in contact with the parts would be likely to produce pyæmia.

#### CELEBRATION OF THE CENTENNIAL ANNIVERSARY OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.

THE minutes of the College of Physicians of Philadelphia begin with the record of a meeting held January 2d, 1787, for the formation of a permanent organization. Of preliminary meetings unfortunately no record remains. Dr. John Redman, the first President of the College, occupied the chair at this meeting and delivered a formal address, which was copied in full with its quaint phraseology and archaic orthography in the minute-book. The names of those instituting the new Society are subscribed to the early records in their own handwriting, and among them are found the familiar names of Philadelphia's leading physicians a hundred years ago. The founders were John Jones, William Shippen, Jr., Adam Kuhn, Benjamin Rush, Thomas Parke, Gerardus Clarkson, Samuel Duffield, James Hutchinson, William W. Smith, Andrew Ross, William Clarkson, James Hall, William Currie, John Redman, John Morgan, George Glentworth, Abraham Chovet, Benjamin Say, Samuel Powel Griffiths, Benjamin Duffield, John Morris, John Carson, John Foulke, and Robert Harris.

Before the charter was obtained in 1789, there had

been added Nathan Dorsey, John R. B. Rodgers, Caspar Wistar, Jr., James Cunningham, Charles Moore, Michael Leib, and John H. Gibbons.

The object of the new organization was stated to be "to advance the Science of Medicine, and thereby to lessen human misery, by investigating the diseases and remedies which are peculiar to our country; by observing the effects of different seasons, climates and situations upon the human body; by recording the changes that are produced in disease by the progress of agriculture, arts, population, and manners; by searching for medicines in our woods, waters, and the bowels of the earth; by enlarging our avenues to knowledge from the discoveries and publications of foreign countries; by appointing stated times for literary intercourse and communications; and by cultivating order and uniformity in the practice of physic."

The history of the College during the past century was distinguished by its consistent and loyal adherence to the best interests of the profession. In the addresses delivered at the celebration a retrospect was given of the course of the College and of the relations which it has borne to the profession and to the community.

The programme of the Centennial celebration was arranged by a Committee, consisting of Drs. Alfred Stillé, S. Weir Mitchell, I. Minis Hays, J. Ewing Mears, and Samuel W. Gross. The principal features were:

"An address by the President of the College given at Association Hall on Monday evening, January 3d, 1887, followed,

"At nine o'clock on the same evening, by a Reception in the College building. To the Address and the Reception invitations to ladies were issued.

"On Tuesday, at twelve noon, a meeting of the College was held at which Honorary Fellowships were conferred upon distinguished members of the profession. Addresses were made by Professors Stillé and DaCosta.

"At half-past six, on Tuesday, the anniversary dinner was given at the Union League.

"A valuable loan exhibition of the portraits of Fellows of the College, with those of distinguished members of the profession, and also a loan exhibition of rare medical books and rare objects of medical interest, was held January 5th and 6th."

The Commemorative Address by S. Weir Mitchell, M.D., President of the College, was delivered before a brilliant audience of ladies and gentlemen, and was received with marked evidence of approval. It was chiefly historical and biographical, but not tedious as such addresses are apt to be. On the contrary, it was elevated in diction and entertaining in its delivery. The orator, in order to place before his audience the condition of the profession at the time of the founding of the College, commenced by reviewing the social life of the century immediately preceding. In those early years, owing to the absence of adverse social limitations and restrictions, the physician, in this new country, found the way open to wealth, social place and even political preferment. In Philadelphia, even more than in the surrounding communities, the physician has, from the first settlement until to-day, held an almost unquestioned preëminence. "He is, and always has been, relatively a more broadly important personage here than elsewhere." Instances were

given of physicians becoming lawgivers, directors of banks and serving on collegiate boards.

Edward Jones and his father-in-law, Thomas Wynne, physicians of culture and gentle breeding, came over in 1682; the latter was an active practitioner of physic, and yet found time to become President of the first Assembly, in which sat his son-in-law, Jones. Thomas Lloyd found time to act as Deputy Governor, President of Council, and Keeper of the Great Seal of the Commonwealth. Griffith Owen, the physician of William Penn, was Member of Assembly, Deputy Master of the Rolls, and Commissioner of Property. Lloyd Zachary, the first physician elected to the Pennsylvania Hospital, was what we now would call Port-Physician, in 1725; sharing this duty with Thomas Graeme, a Scotch physician, who arrived in 1715, and who subsequently received other distinctions, the last of which was that of Chief Justice of the Supreme Court.

The fact that so many of the early physicians were of the Society of Friends may serve to explain why, neither in the seventeenth nor the eighteenth century, are found in Pennsylvania what was very common in early New England and New Jersey, men doubly occupied as physicians and clergymen.

Turning to the subject of the institution of the College, it was observed that many of the founders had been educated at Edinburgh, which is the parent of the University of Pennsylvania. "Genealogically we might speak of our College and of the University as children of Edinburgh and grand-children of Leyden." Short biographical sketches were given of John Redman, "a man whom all men respected and all men loved"; John Jones, the author of the first American book on surgery; Plunket Glentworth, the friend of Washington, who wrote of him, "no nobler man or more skilful physician ever lived"; John Morgan, the founder of the University of Pennsylvania; William Shippen, the associate of Morgan, and able anatomist; Adam Kuhn, the botanist and friend of Linnaeus; Benjamin Rush received an appreciative notice which is best given in the eloquent language of the speaker:

"With reverent doubt of my powers to do justice to the greatest physician this country has produced, I approach the task of briefly recalling to your memories the vivid and emphatic personality of Benjamin Rush. His life invites a less hasty biographer, and is full of such seeming contradictions as can only be explained by the belief that the earnest, decisive, and mutinous nature of a man, proud, rather than conceited, got the better of the principles by which he honestly strove to guide his conduct. That he won at last in this contest, was shown by the grief with which a nation mourned his death, when the poor in crowds besought a sight of his face, or, at least, to touch his coffin. Look at his portrait, by Sully, in our hall. It has the scholar's hands, the largely modelled head, the contemplative blue eyes of the observer, the nose and chin strong, firmness in the mouth, and a trace of too critical tendencies in the droop of the lines of the lips, withal, a general expression of tranquil benevolence, a face like the man's life and character, full of dissimilars, with a grand total of good.

"How shall I briefly bring before you the career of this restless being? Relentless energy drove him through a life in which ardent sense of duty, large-minded philanthropy, love of country, devotion to his art and its science, immense belief in himself, were the motives to industry; which made note-books the

companions of his student youth, and which failed not until the pen fell from a hand enfeebled by the close approach of death.

"He was a statesman, a scholar, an army surgeon, a punctual and careful physician, an actively religious man, a far-seeing and courageous philanthropist, and a sanitarian far in advance of his day. These are what I might call four careers, in all of which he excelled, unaided by secretaries or modern means of condensing and relegating labor: one such suffices most men. He was a member of every important political assembly which met in this State while he lived. When timid men fell out of the Continental Congress, he was elected to that body, that he might sign the Declaration of Independence, and was the only physician whose name is on that energetic arraignment of the Crown. I have neither time nor desire to speak of his relations to Washington. He criticised him with his usual courage and with a severity in which at that time he was not alone, and, although later in life he somewhat relented, he never quite forgot the bitterness which arose out of his too famous letter, and to the end of his days looked upon the great leader as one not above the judgment of his fellows. As regards the patriotism of Rush there can be no doubt. It approached the earnestness of religion, and its very intensity made him unhappy and critical when others seemed to him to be showing that want of energy which in the first years of the war he thought was seen in the Fabian policy of Washington.

"Rush was Surgeon-General to the Middle Department, and later Surgeon-General, and served faithfully in the New Jersey campaign and in the dreary camp at Valley Forge. He resigned in 1778, after his difficulty with his chief, and declined pay for his services.

"As a broad-minded philanthropist, I view him with wonder. The higher education of women he urged as a special need of a Republic, and as boldly wrote of public punishments and against the penalty of death. With like courage he denounced slavery, or turned to demand legislation against the abuse of alcohol, or to implore care in the use of this agent in disease, and, although a scholarly man, eloquently represented the waste of time in the too general study by the young of the classical tongues.

"On his medical career I cannot linger. His views as to bleeding were extreme. They were greatly modified in his later years, but have been misrepresented by the enmity his positive nature excited, and can be fitly judged, not by his occasional vigor of statement but also by the many tempering remarks to be found in his works. His ideas on the contagion of yellow fever and its domestic origin excited the hostility of commerce, and embittered his existence; but, although as to the former he changed his beliefs later in life, as to the latter he seems never to have faltered.

"I presume that he held his opinions tenaciously, and was so conscious of his own general superiority to those about him, that he found it hard to weigh their reasons justly. He says, 'I early discovered that it was impossible for me, by any reasonings, to change the practice of some of my brethren.' Then he adds, 'humanity was therefore on the side of leaving them to themselves, because what is done in these consultations is the ineffectual result of neutralized opinions; for the extremity of *wrong* in medicine, as in morals and government, is often a less mischief than that mix-

ture of *right* and *wrong* which serves, by palliating, to perpetuate evil.' How interesting is this irritable confession, which tells so much more of the man than he meant to put into it. Let me add, as a thoughtful physician, that no one can read what he wrote—and I have read most of it—without a strong sense of his sagacious and intelligent originality, and admiration of his clear and often fervid style. His work on insanity is a masterpiece. A recent English writer calls his book on 'The Bilious Remitting Yellow Fever' a wonder, and says of that remarkable description of his sensations during the height of the epidemic, 'it is as if he were talking to you, a ghostly whispering through a veil of nine-tenths of a century.' He has been called the American Sydenham. He was not as I see it, so great a physician, but taking his whole career—and both were earnest republicans—Rush was the larger personage, and surely, next to Franklin, the greatest citizen of Pennsylvania.<sup>1</sup>

"His bitterest foes are best remembered because of the man they reviled. Even before death came to heal all wounds, he stood where few have stood in the estimate of men. He could not but feel this tribute. It gentled the positive and ardent nature, once ready to cross swords with all who dared to differ. He says 'I was once an aristocrat, then a democrat, now I am a Christocrat.' Certain of his words should have been placed on his tombstone. With them we may leave him to his repose, near the yet greater Franklin. 'Posterity,' he says, 'is to the physician what the day of judgment is to the Christian.'

Among the departed worthies who were Fellows of the College, and served their generation well, was Samuel Powel Griffiths, the editor of the *Electric Repository*, and the able coadjutor of Rush in sanitary and philanthropic work. "Wherever he went and in whatever he did peace and gentleness were round about him, so that in every relation of life, men and women eagerly trusted this simple, straightforward, intelligent, unambitious man. Caspar Wistar, Jr., the successor of Shippen, in the chair of anatomy, in the University, had the distinction in 1811, of publishing the first native treatise on anatomy in this country. The Wistar parties, which have filled such a conspicuous place in the social life of the profession in this city, were founded by him. The last of those elected previous to the incorporation of the College in 1789, was Michael Leib, who after honorable services in the yellow-fever epidemic, left the profession to become a leader in the Democratic party, and served in both houses of our National Congress."

The orator next took up the public services of the College, its early adoption of a Code of Ethics, its care for vital statistics, and meteorological records, its studies of epidemics, and letters of advice with regard to the great outbreak of yellow fever in 1793, which he then graphically described. Many of the physicians died and none were left untouched by the plague. Says Rush, "At one time but three physicians were able to do duty outside of their own houses. From this cruel summer until 1806, no year left us free from the fever, but the worst of it fell upon us in 1798." Hutchinson, Morris Griffiths, and later Hugh Hodge

<sup>1</sup> Rush left letters, diaries, and also biographic memoirs of his contemporaries, without which, no man can fitly judge him or them. Friends, relatives, and executors have been chary of publishing these records. Some of them I have read, and I think it only just to a great man that we should know all that there is of him to know. He was too great, too productive, too various to lose esteem on account of anything he may have said or written of Washington.

and Annan perished. "The horrors of 1825 with its small-pox, and the cholera of 1832 found the successors of these men as able, as simply ready, as courageous."

After a short period of apparent paresis the College, from 1824, had fortunate accessions of new and notable names, Harthorne, Bond, Hodge, Meigs, La Roche, John K. Mitchell, Darrach and notably Wood and Bache, and Pennock Gerhard, Hays, Pancoast, Mütter, Carson, Dunglison, Norris, McClellan. The present College home is due chiefly to the liberality of George B. Wood, of George Fox, and to the unceasing efforts of Isaac Hays, as chairman of the Building Committee. The Mütter bequest, of a valuable collection of pathological preparations and specimens, with \$30,000 endowment to keep it in order, stipulated that a fire-proof shelter should be provided. This stimulated the building fund, to which Dr. Wood gave not less than \$10,000. The library, which owed its first gift and legacy of books to John Morgan, now numbers nearly 38,000 volumes and some 20,000 pamphlets, with an annual growth of some 25,000 volumes, with thousands of pamphlets, and 325 current medical periodicals. The debt of the library to Dr. Samuel Lewis, who is still living, was gracefully and heartily acknowledged.

In that last great war "whose authors we do well to forgive, but whose trials and lessons we do as well never to forget, this College was true to its traditions. There are on our list to-day, at least 104 men who served their country in the field, in hospitals, or at sea, in those years of sacrificial trial.

"Whatever we may have thought or felt of that section of our race which faced us in fight, of this at least I find it a pleasure to feel sure, that wherever men were sick or wounded, our ancient guild did well its Christ-like duty. As to that record, North and South, there can be neither doubt nor difference.

"I close with satisfied pride these annals of the past, and its dead. I see about me men whose books are in every tongue of Europe, whose works are known and honored among the learned of every land, men who wear by just decree of their fellows the unseen crowns of honorable estimate. I see, too, the young in work, the men who are to follow us. To them we shall soon consign this precious heritage, the record of a century of duty; a hundred years without one break in our meetings save when pestilence thrust upon us a more imperative service. There is that in these years to make them proud of a fellowship which in war and in peace has left us examples of single-minded workers unknown to fame, of the charity without taint of selfishness, of heroic lives lost in battle with disease, of gentle scholars, of daring surgeons, whose very fingers seemed to think, of physicians rich with every professional grace. The pride of lineage is valueless which does not secure to the future vitality of usefulness, and I must have told my story ill if to every physician who hears me its illustrations have not the invigorating force of moral tonics.

"I turn now from the present and face the silence of futurity. As earnestly as our first president, I pray with him that all those who sit around me, and all who are to come, do publicly and privately serve their generation.

"Feeling, like him, the weight and dignity of my office, and to-day more than ever, I look onward

thoughtfully to that next centennial time. Every heart that beats in this hall to-day will have ceased to pulsate. Another will stand in my place. Reviewing our works and lives, he will be able, I trust, to say as confidently of us as I have said of your fathers—these, too, belonged by right of dutiful lives and sincere work, to our great, undying brotherhood."

After the Address a Reception was held at the Hall of the College, at which were present many distinguished members of the profession from other cities.

At noon, January 4th, a special meeting of the College was held, and Prof. Alfred Stillé read some interesting "Reminiscences of the College of Physicians of Philadelphia." A retrospect of the gradual growth of the institution, its vicissitudes and later achievements, with personal recollections of departed Fellows, but chiefly an historical account of the wonderful development of the library, were the subjects treated by the essayist. The public spirit of the College during the century was shown by its memorials to the Legislature and municipal government upon the subject of vital statistics, the importation and sale of drugs, the management of the City Hospital, the sewerage of Philadelphia, its park and its water-supply. It adopted a Code of Ethics in 1843, which was subsequently substantially adopted by the American Medical Association, it aided in forming the State Medical Society, and the City Board of Health, and has established a Nurse Registry Bureau which has been found to be a great public convenience. It also memorialized the Legislature to legalize dissection, and the present law took its origin in this action of the College. It took a prominent part in the celebration of the National Centennial in 1876. It memorialized Congress in 1850, for a law for the inspection of drugs; and later, with regard to the formation of a National Board of Health; the publication of an Index Catalogue of the Library of the Surgeon-General's Office; the furnishing of a fire-proof building for the Army Medical Museum. The spirit of the College is well expressed in its motto "*Non sibi sed toti*."

At the conclusion of the Address, the President introduced and conferred the diploma of membership upon the newly-elected Associate Fellows: Henry P. Bowditch, M.D., of Boston; David W. Cheever, M.D., of Boston; William H. Draper, M.D., of New York; R. Palmer Howard, M.D., of Montreal; Hunter McGuire, M.D., of Richmond; John C. Reeve, M.D., of Dayton; Nicholas Senn, M.D., of Milwaukee; George C. Shattuck, M.D., of Boston; T. Gailard Thomas, M.D., of New York; James T. Whitaker, M.D., of Cincinnati; David W. Yandell, M.D., of Louisville.

The Address of Welcome to the new Associate Fellows was delivered by J. M. DaCosta, M.D., LL.D., who, after briefly referring to the changes wrought in social and civil life during the past century, said:

"Our age is an age of zealous investigation and active change. Newly-elected Associate Fellows, we find represented in your ranks what, in these days, we chiefly honor in our many-sided profession. We find learning and order, but we also find love of research, originality, boldness; we note you quick of eye, fertile of resource, independent of thought, and, if we have singled you out on this occasion, it is because you are the type we delight in, the true children of our time and tendencies.

"How will it be when another hundred years have

passed away? Will the best traits that have made our investigators eminent go to form the cast of a medical mind reaching out into now unseen worlds of science, and looking, with eyes keen with suggestive research, at every line on every page that age has seasoned? Or will all knowledge be so plain and elementary that its application alone will be cared for, and investigation be regarded as nearly complete? It is not likely. The stone thrown into the water gives rise to ever-increasing rings; and so must it be in pursuits in Nature. There is still a greater world beyond the microscope and the telescope than we know with it.

"Associates, in joining you to us to-day, we bestow on you all this College has to bestow. It gives you full share in all that a century of learning, of culture, of pure aims, of renown, of high tone, most zealously guarded, has done to make it famed and respected. On its part, it takes a mortgage on your past acquisitions, as well as lays claim to a portion of the results of your future work. And when some fresh, thoughtful deduction in practical medicine becomes the theme of every pen; some new, life-saving operation is everywhere discussed; some clear monograph of exhaustive research and wide grasp is by every one lauded; some ingenious application of physiological experimentation laid before the world; when we hear of a celebrated treatise of a great practical master being translated into yet more tongues — we shall feel the pride of possession in our Associate Fellow, and, rejoicing in his success, claim him, for the College, as among our own. These are the feelings we have toward you, and we now greet and welcome you as sons of this old institution with all the love of brotherly affection."

The essayist concluded his very interesting address in the following words:

"In this partial retrospect of the history of the College during the last forty years, one can hardly fail to note that in it, as in political and social, and, indeed, every history, progress has depended upon individuals. The hour must come, and the man must arise, who, by his voice or his example, stimulates other men to vigorous and fruitful action. As in its infancy the great name of Rush dominated the College, through his inventive genius and foresight, so in its later history George Bacon Wood ruled it by his wisdom and liberality; another has made illustrious his living name by opening a rich mine of intellectual wealth for all seekers after knowledge; and still another is distinguished for his liberality in promoting the social, artistic and literary tastes of his fellow-members. All, by their example, have so warmed the enthusiasm and quickened the sympathies of the Fellows, that this commodious building, this precious scientific museum, and this noble library, have sprung into existence in the brief space of a single generation.

"Let us hope that so fair a flower of science shall not languish through indifference, neglect, or indirection, and that at the end of another century our posterity shall be able to speak of us with unstinted praise, and with as sincere gratitude as we now feel toward those who prepared the way for this goodly habitation and temple dedicated to the service of humanity."

At the close of the exercises, luncheon was served.

Limits of space forbid extended reference to the Loan Collection, or even the enumeration of the many valuable portraits of the founders of the College, and

of distinguished members of the profession, both in and out of its Fellowship; or of the many objects which it contained of medical interest, a printed catalogue of which was provided by the Committee.

The dinner was given on Tuesday evening, in the spacious Assembly Room of the Union League. There were one hundred and thirty covers, and fourteen courses were attractively served, but the chief features of the occasion were the responses to the toasts, and an original Commemorative Ode by the President. All who were present were physicians, and, with few exceptions, either Fellows or Associate Fellows of the College. Among those in attendance from a distance, were Drs. George C. Shattuck, Boston; T. Gaillard Thomas, New York; Hunter McGuire, Richmond; R. Palmer Howard, Montreal; William H. Draper, New York; Fordyce Barker, New York; A. M. Pollock, Pittsburgh; R. S. Ives, New Haven; E. Darwin Hudson, New York; Nicholas Senn, Milwaukee; James F. Chadwick, Boston; David W. Cheever, Boston; George B. Shattuck, Boston; J. T. Whitaker, Cincinnati; Wm. W. Phillips, Trenton, Iraill Green, Easton; J. S. Billings, U. S. A., Washington; Henry P. Bowditch, Boston; J. C. Cameron, Montreal; A. H. Halberstadt, Pottsville.

The Loving Cup was sent around at the end of the last course, and toasts were in order. The sentiments proposed by the President were:

The "Founders," which was drunk standing and in silence; Dr. Hartshorne made a brief address.

The "Fellows," responded to by D. Hayes Agnew.

The "Associate Fellows," replied to by T. Gaillard Thomas.

The "Physician," William Pepper, Provost of the University of Pennsylvania.

The "Surgeon," John Ashhurst, Jr.

The "Obstetrician," Theophilus Parvin.

The "Medical Societies of America," by John S. Billings, U. S. A.

The exercises concluded by the reading of commemorative stanzas written by the President for this occasion.

### Recent Literature.

*A Treatise on Electrolysis and its Applications to Therapeutical and Surgical Treatment in Disease.* By ROBERT AMORY, A.M., M.D. 8vo, pp. vii, 307. New York; William Wood & Co. 1886.

This is the volume of Wood's Library for August, a thing to be regretted as the book is therefore less accessible. The subject of electrolysis is one that has heretofore received little consideration in works on electro-therapeutics; Erb, if we mistake not, barely refers to it, and De Watteville gives it but five pages. The present work, we believe, is the only one devoted entirely to the subject. The author therefore dwells at length and perhaps somewhat too diffusely, upon the physical and chemical principles involved in electrolysis, and gives full details of the pathology of the diseases mentioned. This fulness of detail, however, if it be a fault, merely renders the work more exhaustive. Several chapters, too, are devoted to the principles of electrical science, and afford much valuable information as to the different forms of cells and the various appliances for the proper use of electricity. We regret to see that the author continues to use the mis-

leading and obsolete terms "quantity" and "tension" because they "will be better understood." The result is often confusing to those who have discarded those terms as meaningless. The practical application of electrolysis is illustrated by many cases quoted from different writers, and by cases from the author's own experience. In his own hands it has given brilliant results in the treatment of exophthalmic goitre and in the removal of superfluous hair. It has proved of advantage, too, in the treatment of aneurism and of every form of hypertrophic normal growth. We are sorry that the author has not given a more full account of its use in stricture of the urethra, now so much discussed, especially as he differs from several recent writers in preferring the kathode for local application. Since the use of electrolysis demands special skill and considerable outlay for batteries and appliances, its application must naturally remain in the hands of specialists; but the value of electrolysis is unquestionable, and we trust that this book may bring to the notice of those who have the necessary knowledge of electricity an appreciation of its value as a therapeutic agent. The mechanical execution of the book is much above the average of Wood's series.

*Hémorrhagies Uériques. Étiologie — Diagnostic — Traitement.* Par LE DOCTEUR SNEGUIREFF, de Moscou. Édition Française. Paris, 1886.

The title of this work hardly does justice to its scope and comprehensiveness. The writer has aimed to give a study of the hæmorrhages to which woman is liable during her whole life, and inasmuch as uterine hæmorrhage is a very frequent symptom of several important affections, and an occasional accompaniment of a large majority of diseases of the pelvic organs, the result is an extensive treatise on gynecology. The first part of the book is devoted to a description of the method in general followed by the author in making his examination. He then considers the etiology of uterine hæmorrhages, dividing them into organic and reflex. The organic he classes as follows: (1) malignant growths; (2) benign growths; (3) chronic inflammations (metritis and endometritis); (4) abortion, pregnancy, puerperal diseases; (5) displacements of the uterus; (6) ovarian apoplexy and hæmorrhages of the pelvic peritoneum; (7) the menopause; (8) general disturbances of nutrition. The treatment is divided into two sections: (1) Treatment of uterine hæmorrhages in general; (2) treatment of the different affections which cause the hæmorrhage.

As will be seen from this brief résumé of the contents of the book, it takes a wide range; at first glance, perhaps too wide. But on the whole, in these days of the multiplication of extended treatises on gynecology, a work which taking a single prominent symptom looks at the diseases of women solely with reference to that symptom alone, is both instructive and refreshing.

The author has done his work well. He is well-grounded in German methods and ideas, but is also original. There is very little to take exception to in any portion of the book. The part which deals with general treatment of uterine hæmorrhage is perhaps most fertile in suggestions. The author places a great deal of dependence, and justly in the light of his experience, upon the use of hot and cold baths, general and local, and upon prolonged courses of hydropathic treatment at the various famous baths of Europe. The book is well worth reading.

## THE BOSTON Medical and Surgical Journal.

THURSDAY, JANUARY 13, 1887.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 283 Washington Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES, UPHAM & COMPANY,  
283 WASHINGTON STREET, BOSTON, MASS.

### COLLECTIVE INVESTIGATION ON CENTENARIANS.

THE late Dr. Farr has shown, in his "March of an English Generation through Life," that one million children born in England live forty million, eight hundred and fifty-eight thousand, one hundred and eighty-four years, that two hundred and twenty-three live to the age of one hundred, and that finally at the age of one hundred and eight, one solitary life dies.

In the supplement to the *British Medical Journal*, of December 11th, Prof. Humphry has analyzed the returns from reliable medical men regarding fifty-two centenarians tabulated from the results of a form of inquiry issued by the Collective Investigation Committee of the British Medical Association. In only eleven was the age confirmed by any official record, but the others were naturally assumed to have at least reached nearly the age of one hundred, the informant, in each case being competent to estimate the value of the evidence, and in most of the cases being intimately acquainted with the individual.

In eleven the intellect is stated to have been high, and low in only five; twenty were reported strong, sixteen of average strength and twelve feeble. Thirty-six were women, sixteen men, — a fact explained by Mr. Humphry partly by the fewer exposures of women, notwithstanding the dangers incidental to childbearing and the diseases associated with the varying demands made at different periods, upon the organs connected with that process; and partly also by the greater inherent vitality in the female.

Of the thirty-six women, twenty-six had been married, eleven had large families, and eight married before they were twenty, one at sixteen and two at seventeen. Many of the centenarians were members of large families, there being but two designated as only children. Forty-one of the fifty-two had been married. Twelve were first children. The parents of one centenarian were first cousins.

The average centenarian qualities were a good family history, a well-made frame of average stature, spare rather than stout, robust, with good health, appetite,

and digestion, capable of exertion, good sleepers, of placid temperament, and good intelligence, with little need of, and little consumption, of alcohol and animal food, although one man always did and "always will" drink to his utmost capability.

Three were affluent, nineteen poor, and twenty-eight in comfortable circumstances.

Twenty-four of the centenarians had no teeth, and the average number retained was only four or five. Twenty-eight used glasses, but thirty-five, including many who used glasses, were reported to have been in the enjoyment of good sight. Hearing was good in twenty-two, indifferent in seventeen, bad in nine, one was deaf.

The majority were moderate or small eaters, but maintained an average pulse of 70°, and respiration of 22,—a fact explained by the diminished elasticity of the circulatory and respiratory apparatus. The arteries had become less capable of accelerating the blood-stream, and the vital capacity of the chest was much reduced, as shown in the slight difference in the chest-girth between the state of inspiration and that of expiration. The hours of sleep averaged nearly nine, the extremes being twelve and four.

The brain held out as well as the other organs, perhaps better; two only were demented. The weakness or failing, generally, seemed to have been about equal in the several great organs.

The majority had suffered little from illness at former periods, yet some had recovered from severe diseases. The habits of life were generally such as conduce to health, necessitated in a measure, at least, by some from their occupations. Thirty-two did not use tobacco; twelve were total abstainers from alcohol, twenty took little, eight drank moderately, one drank to excess on festive occasions, one was a free beer-drinker, and one "drank like a fish all his life" when he could, but said also that he could not get much.

#### REMOVAL OF THE UTERINE APPENDAGES AND THE LIVERPOOL HOSPITAL FOR WOMEN.

THE question of the removal of the uterine appendages has a distinctly ethical as well as surgical aspect. The former is growing in importance if we may judge by the increasing frequency with which this phase of the subject is discussed in medical literature, and by some distinctly practical results of a decidedly unpleasant character, which have occurred both in this country and Great Britain.

One of the secondary outcomes of this question has been engaging the attention of medical men in England the past year, in connection with the Liverpool Hospital for women, and though the final stage may not have been reached, yet it may be of interest to briefly review the course of events thus far.

Dr. Francis Imlach, one of the surgeons to the Liverpool Hospital for Women, performed an operation for the removal of the uterine appendages in a

case of intra-peritoneal hæmatocele. The patient recovered, but subsequently sued Dr. Imlach on the ground that the operation was unnecessary and performed without knowledge on her part of its nature. The case came to trial in August, 1886, and after the evidence on both sides was in, the jury without leaving their seats returned a verdict for the defendant.

In February of the same year, whether, which is probable, because the fact of this suit having been brought was known, or for the reason alleged that the number of operations included under the term abdominal section, had risen from eighty-six in 1884, to one hundred and sixty-six in 1885, and such increase was considered "remarkable," a committee was appointed by the Liverpool Medical Institution to inquire into the matter.

The resolution under which the committee was appointed stated that "In view of the large and increasing number of cases of abdominal section in the Hospital for Women in this city, as shown by the Annual Medical Report for the years 1884-5, this meeting is of opinion that a special committee be appointed for the purpose of investigating the grave question of practice and ethics involved in the performance of these operations, and to report at a future meeting." The committee was composed of eight surgeons and physicians connected with the large hospitals of Liverpool.

Just what relation the Institution holds to the medical profession in Liverpool, and with what authority such an investigation into the methods of a hospital could be prosecuted, we have no means of knowing. It is said that the "medical staff of the Hospital for Women present, took an active part in the discussion, and voted for the proposed committee," and that "at a subsequent period it was deemed right that the medical officers of the Hospital should each if they wished send a representative to the committee to watch their interests." Suffice it to say the committee did make a thorough investigation, the results of which are embodied in a report published in the *Lancet* of December 11th, 1886.

The plan of investigation included the reports of the medical officers of the Hospital, supplemented by notes of the condition of the patients as ascertained by subsequent visits; information received from medical practitioners in and around Liverpool, who had patients under their care either before or after operation at the Hospital; personal visitation of some forty or fifty patients by members of the committee; certain specimens of ovaries and Fallopian tubes removed by Dr. Imlach; the appointment of a sub-committee to personally examine the Hospital records, and question the lady-superintendent and nurses.

As a result of their investigations they found that there had been one hundred and six abdominal sections performed for the removal of the uterine appendages. Ovariectomy, exploratory incision, and oöphoraphy, which comprised the rest of the one hundred and sixty-six, did not call for any special comment.

With regard to the first series the committee arrived at the following results: (1) Danger to life. The mortality was eight or nine per cent., and the committee sagely concludes that if the operations were done for grave disease, and the patients were generally cured, such a mortality was not high, but if done for trivial affections, and the patients were generally not benefited, it was. (2) Sterility. As this is a necessary result of the operation, it should be clearly explained to the patient, and her relatives. (3) Loss of sexual feeling, and of physical energy. The committee found a comparatively small number who complained of these effects. (4) Hernia. Out of one hundred and sixty-six cases, fifteen were found in which hernia resulted. (5) Actual results to the patients. The committee found distinct and permanent benefit in about half the cases, slight or temporary benefit in nearly as many, and positive injury claimed in a few.

In view of the above facts, the committee were of the opinion "that at the Hospital for Women sufficient care and discrimination had not been exercised in the selection of cases for operation, and that in many instances the gravity of the symptoms was not such as to have justified an abdominal section of any kind." They recommended consultations before any abdominal operation, full information to patients of the nature and consequences of the operation, and longer retention in the Hospital after operation.

Dr. Imlach, whose unfortunate lawsuit was apparently the "*fonc et origo*" of this investigation, and against whose methods the criticisms of the committee were mainly directed, inasmuch as he performed eighty-five out of the one hundred and six operations, has sent a letter of protest to the *Lancet*, which is published with the report of the committee, and it is only fair to briefly outline the points he makes. He claims that the committee was not composed of men who could fairly be supposed to be unprejudiced; that he wished to be represented on the committee by a pathologist, but the one he selected declined, as he did not approve of the method of appointment of the committee; that the disease for which he performed the operation in the case of the patient who subsequently sued him, though held by the committee not to be one for which abdominal section should be performed, is regarded by most leading gynecologists as liable to develop grave or fatal symptoms, and to be one for which laparotomy is frequently indicated; that the question of the justifiability of the operation depends upon the severity and persistence of symptoms, and the pathological changes found in the organs; and that the committee failed to mention that he had "treated sixty-seven cases of inflammatory disease sent in with a view to operation, solely by rest and medical means." There are many minor points which Dr. Imlach alludes to, which seem to indicate pretty clearly that the investigation, though apparently thorough, was not conducted in a spirit of perfect fairness towards the surgeons of the Hospital.

What is the general impression conveyed by this whole transaction? What good has it accomplished or can it accomplish? It may serve, perhaps, to emphasize more strongly certain secondary considerations in connection with operations of this character, such as the importance of not operating until other means had been tried and failed, the advisability of the patient and her friends thoroughly understanding the nature and results of the proposed operation, and the help in estimating the value of the operation by keeping the patient under observation for some time after it. But when we consider the class of patients who present themselves at large public hospitals with this class of affections, women for the most part ignorant, many of them degraded, often with a distinctly nervous element predominating, it seems absurd to suppose that any investigation which depends largely upon the statements of such women for its facts, should be considered a suitable way of arriving at just conclusions.

Had the committee been able to question and examine these women before operation, and to see the specimens when removed, then their decisions would have been entitled to respect. The first they were of course unable to do, and the second they seem to have neglected in the cases which they might have examined, as no mention is made in their report of the pathological specimens laid before the committee by Dr. Imlach. In fact, this wise body of men seem to have expressly acknowledged the weakness of their position in this clause of their report: "The Committee regret that from a scientific point of view they are unable to give any very definite assistance to the medical profession in judging of the class of cases appropriate for the operation under consideration, in advance of what is already known and admitted," and yet they condemn these surgeons for having in many cases operated unjustifiably. Candid men must judge how fair such condemnation is. Our verdict would unhesitatingly be, "Not Proven."

While it is true, as has been intimated above, that the attending surgeon at a woman's hospital cannot be too circumspect in advising any radical uterine operation, without making sure that the patient is fully informed as to the actual nature and potential consequences of the operation advised, it is also true that committees of investigation, and other persons who may be placed in the position of critics, cannot exercise too much care against making any report which may increase the grave perils to which the practicing gynecologist is already exposed from designing women.

#### THE CENTENNIAL OF THE COLLEGE OF PHYSICIANS OF PHILADELPHIA.

THE celebration last week in Philadelphia of the one hundredth anniversary of the founding of the College of Physicians of that city was an occasion of more than local professional interest. Our report of the proceedings gives an abstract of the President's vivid review, addressed to a general audience, of a

medical century in Philadelphia as embodied in the active, useful, and responsible lives of the founders, and distinguished members of the College, especially in the first half of the century since 1787—a retrospect continued and amplified for the second half of the century by Dr. Alfred Stillé, a former President, in an address delivered the next day before the Fellows of the College. A reception at the College followed Dr. Mitchell's address, and after Dr. Stillé's address diplomas of associate membership were conferred upon distinguished representatives of the profession selected for the honor from various parts of the country. The celebration terminated with a banquet, to which one hundred and twenty members and invited guests sat down. During the two days an extremely interesting and instructive loan collection of portraits, all of medical men, if we except one of Benjamin Franklin, was open to the public.

The programme, as arranged, was worthy of the occasion, and was very successfully carried out; but such festivities represent something more than mere self-congratulation at the completion of a century, or than the gratification of an instinct for generous hospitality. They represent for Philadelphia an acknowledgment of the many advantages which have accrued to the medical profession and to the public from the existence and the prosperity of the College; to the stranger, who was within her gates, they should represent the wisdom and importance of founding and fostering similar institutions elsewhere.

A suitable building where physicians of rival medical schools, of different views and different modes of practice may meet and discuss the questions of the day face to face on neutral ground; where medical societies may convene in proper halls surrounded by books, by a museum, by portraits of distinguished worthies of previous generations—such a building is needed in all our large cities. It should be under the control of a corporation representing the energy and the liberal intelligence of the medical profession in the community, of a body of men actuated by the spirit as well as the letter of the motto, "*Non sibi sed toti.*"

Such a corporation would exercise needed authority and would be often appealed to by a perplexed public in questions of State, of preventive medicine, and might even succeed to some extent in realizing the last clause of the comprehensive list of objects given for the foundation of Philadelphia's College, namely: "The cultivation of order and uniformity in the practice of medicine." New York has such an institution in process of development in the Academy of Medicine; in Boston the Medical Library Association offers the possibility of a similar evolution; but the College of Physicians of Philadelphia in its past history, its present organization and equipment is *facile princeps*, if not alone, among such institutions as we have pictured and would like to see flourishing in our large cities, especially in such as are centres of medical thought and education.

#### A NEW TREATMENT OF GONORRHEA.

CASTALLAN, of St. Mandrier Hospital, starting with the view, now popularly entertained, that gonorrhoeal urethritis is a parasitic disease, and being led by observation to believe that the microbe can only live in an acid medium; finding, moreover, that in this disease the discharge is, as a rule, acid, proposes to treat gonorrhoea in the acute stages by urethral injections of sodic bicarbonate; three or four injections being made daily of a one per cent solution.<sup>1</sup> For this treatment, which is but a logical inference from the premises, he claims remarkable success, although the cases on which it has been tried in St. Mandrier, as yet, number only a dozen. The injections of bicarbonate of soda are commenced as soon as the discharge appears, or the patient comes under observation; the urethral secretion is tested every day with litmus paper, and the injection is kept up till the discharge becomes alkaline or neutral. For internal treatment the patient is given flax-seed tea, with occasional doses of bromide, if there seems to be any indication for the sedative effects of this salt. His conclusions are as follows:

(1) The urethral pus in the first stages of the disease is generally, if not invariably, acid; this acidity is quite pronounced.

(2) The treatment by bicarbonate of soda rapidly lessens the discharge; it also rapidly diminishes or removes the pain in micturition.

(3) In old urethritides, and in those which have been treated by the usual injections, it speedily brings about a cure.

#### DEATH FROM COCAINE: A RESULTING SUICIDE.

It has not heretofore been accurately determined what dose of cocaine is dangerous, or how far its application to various mucous surfaces, as the rectum, may be carried with safety. In one case reported by Delafosse, forty-eight grains were introduced into the rectum for the purpose of producing local anaesthesia during the curetting of a tuberculous ulceration; the operation was successful. A similar case lately came before Professor Kolomnin, of St. Petersburg, a young and brilliant Russian surgeon. In order thoroughly to scrape and cauterize the rectum, which was the seat of a tuberculous ulcer, cocaine was employed in just half the quantity previously used by Delafosse. Twenty or thirty minutes afterward, symptoms of poisoning declared themselves, syncope and complete collapse set in, and in spite of stimulants, injections of ether, faradization, artificial respiration, etc., the patient died.

So chagrined and overwhelmed with horror was the unfortunate surgeon at this accident, that he committed suicide. The details are given in a long letter from Professor Artzrouni to the *Sémaine Médicale*, and the whole melancholy history has been laid before the St. Petersburg Medical Society by Professor Botkin.

<sup>1</sup> Bull. Gen. de Théor., December 15, 1886.

## MEDICAL NOTES.

— It is said that some 200 different cures for rheumatism have been sent to President Cleveland since his late illness.

— Dr. A. Favre, of Fribourg, says the same writer, describes an interesting case of rupture of the gravid uterus during labor at full term. It occurred in a pauper woman, aged thirty-three, who was suffering from osteo-malacia, with extreme contraction of the pelvis. The true state of things became evident only when laparotomy had been performed. A dead fetus and placenta with membranes were found floating in the peritoneal cavity, whilst the womb was firmly contracted to the size of a child's head. The site of the rupture could not be ascertained. The abdominal wound was closed by suture, no provision for drainage being made. Recovery took place without an unfavorable symptom, the highest recorded temperature being 38.5° C. on the third day. Fifteen days after delivery, the patient was up and about.

— The *New York Medical Journal*, after referring to the brilliant war of words that once took place between a Billingsgate fishwoman and a scholar, in which the latter made use of mathematical terms that his adversary could not match, cites, as not precisely in the same line, but evidently quite effective, an expression of disgust lately applied by a woman to a Paris policeman, "*Tu me fais l'effet d'une pilule!*" This pharmaceutical abuse was more than the policeman could endure, and the woman was brought before one of the police courts, where, according to a Paris dispatch to the *London Daily Telegraph*, she was acquitted on the ground that there were a thousand kinds of pills, the effects of which were of the most varied character, but she had not mentioned any particular kind. "So we may infer," the account continues, "that, had Ernestine Roussel compared her enemy to a blue pill, for instance, she would have been treated with more rigor."

## BOSTON.

— The statement in the recent address of the President of the College of Physicians of Philadelphia, that Rush "was the only physician whose name is on that energetic arraignment of the Crown" (the Declaration of Independence) should not pass unchallenged. Josiah Bartlett, of New Hampshire, and Lyman Hall, of Georgia, were successful practising physicians; Oliver Wolcott, of Connecticut, studied for the profession.

— The "Living Skeleton," pleasantly and familiarly known to some of the attendants at Dr. Holmes's anatomical lectures, has at last become a dead skeleton. Mr. Sprague, the individual in question, has just died, at the age of forty-six, and the weight of 40 lbs. He has bequeathed his remains to the Harvard Medical School, and it is to be hoped we shall soon know what was the missing link in his assimilative

system. The deceased was personally inclined, as we remember, after considerable association with admiring medical men throughout the country, to attribute his difficulty to atrophy of the thoracic duct.

— At the twenty-sixth annual meeting of the Obstetrical Society of Boston, held January 8th, 1887, the following officers were elected for the ensuing year: *President*, Dr. William L. Richardson; *Vice-Presidents*, Dr. O. W. Doe, Dr. John Homans; *Treasurer*, Dr. E. J. Forster; *Recording Secretary*, Dr. C. M. Green; *Corresponding Secretary*, Dr. J. Stedman; *Prudential Committee*, Dr. William Ingalls, Dr. J. G. Blake, Dr. F. W. Draper, Dr. J. W. Elliot, Dr. C. M. Green, *ex-officio*; *Publishing Committee*, Dr. Alfred Hosmer, Dr. J. R. Chadwick, Dr. C. E. Stedman. Dr. W. W. Wellington, of Cambridge, was elected an honorary member.

## NEW YORK.

— Mr. Cornelius Vanderbilt has given a donation of \$500 to the St. John's Riverside Hospital at Yonkers.

— Up to January 7th the returns from the Annual Hospital Saturday and Sunday collection show the handsome sum of \$36,464.

— The Commissioners of Charities and Correction have appointed Dr. E. C. Dent, Medical Superintendent of the City Insane Asylum on Blackwell's Island, and Dr. A. Trautman, Medical Superintendent of the Asylum on Ward's Island.

— Governor Hill, in his annual message to the Legislature, has again recommended the abolition of the State Board of Health and the State Board of Charities, and the concentration of the honors of these boards under single heads.

— The Committee on Hygiene of the Medical Society of the County of New York have waited upon the Board of Health in a body for the purpose of urging upon them the passage of an ordinance requiring the baling of all stable-manure in the city; the Board has as yet arrived at no decision in the matter.

— During the past week Joseph Mauri, a Brooklyn druggist, and his seven children were attacked with malignant hemorrhagic small-pox, and three of the children died within twenty-four hours. The true character of the disease was not recognized until after the death of the three children, when the father and remaining children were removed to the small-pox hospital at Flatbush, where the former died in a few hours. Considerable blame is attached to the Brooklyn sanitary authorities, as the three deaths occurring in such rapid succession were supposed at first to be attributable to poisoning of some kind, and the reporters of all the papers were permitted to visit the house and freely communicate with the family. It is needless to say that there has been a lively demand for vaccination by these gentlemen since, and in one newspaper office forty editors, reporters and composers were vaccinated. It is said that a pet cat owned

by the Mauri children, and which slept on the bed with two of them during their illness, has disappeared, and all efforts to trace it have proved fruitless. There has been a considerable amount of small-pox in Brooklyn for some months past.

### Miscellany.

#### HOW SOME SPECIAL HOSPITALS ARE FOUNDED.

THE *Hospital*, a weekly publication, the organ of the Hospitals Association of London, casts a not ill-aimed shaft at a tolerably common device of the young specialist who is looking for a job and who joins to himself a professional "organizer" to present the subject to a charitable public. The latter person evolves and circulates the following manifesto:

#### FREE DISPENSARY FOR DISEASES OF THE LITTLE TOE.

— Street, — Square.

In the year 1883, 30,807 persons died of diseases of the little toe. This number (which includes cases of gangrene, pyæmia, phlebitis, and bunion) is exclusive of the very numerous deaths from wasting diseases and cancer of the digit. (See *Registrar-General's Report*.)

According to the above extract, diseases of the little toe have occasioned more deaths in England than diseases of any other organ, and a comparison of the returns for 1883 with those of the previous years show that these diseases are increasing in a ratio greatly out of proportion to the increasing population.

#### Deaths from Diseases of the Little Toe.

1874.....13,446	1877.....17,908	1880.....21,915
1875.....15,401	1878.....19,634	1881.....30,940
1876.....15,009	1879.....20,879	1882.....24,802
1883.....	.....30,807	

Besides the above number of fatal cases, there is a still greater number of diseases of the little toe not terminating in death, but which give rise to extreme suffering and misery, especially among the poorer classes. *This is the only institution specially devoted to the treatment of diseases of the little toe, and the fact that in less than two years upward of 10,560 patients (from all parts of England) have been relieved, proves that it is a necessity. The employment of the newly invented instrument (the little-toe scalpel) is a special feature in the institution, and by the aid of this instrument morbid conditions of the digit can be fully exposed and adequately treated. Further aid is required to meet the urgent demands caused by the daily increasing number of out-patients. It is likewise essential that a ward should be speedily opened for the reception of the more acute cases. At least £1,000 is required to establish a ward containing six beds. For this purpose the committee have determined to open a new subscription list. Those who desire to assist in this particular way will please notify that their subscriptions or donations are to go to the "ward fund." The benevolent are respectfully informed that the very existence of the institution will be jeopardized unless the funds are considerably augmented.* JEREMIAH DIDDLEB, *Secretary*.

ice applied; during night convulsions affecting left side mainly; patient semi-unconscious for three days, and occasionally showing symptoms of irritation; wound discharged offensive matter for a few days, then healed; at the end of a week seemed nearly well; but fourteen days after the injury, vomiting occurred, followed by convulsions and high temperature. Condition on admission to hospital—Thin, pale, weak, peevish, irritable, restless; lies doubled up in bed; scar on right frontal region, with sinus, from which a small quantity of pus exudes; bare bone distinctly felt. Under an anæsthetic a free crucial incision was made over the seat of injury. A triangular piece of loose depressed bone was removed, permitting the escape of about a drachm of fetid pus. Dura mater thickened, but apparently uninjured. Parts thoroughly washed with carbolic lotion (one to twenty), and dressed with carbolized gauze. Hernia cerebri appeared on third day after operation. Next day child was anæsthetized and the wound enlarged, when another piece of dead bone was discovered and removed. The flaps of skin were stitched over the hernia to repress it. Child somewhat better. After this the child did well, and was discharged two months after the injury apparently quite well, but with a sinus still remaining, which discharged some pus. On 1st August, five months after the injury, the child had an attack of convulsions affecting the left side. The face most marked, and the upper more than the lower extremity. She was at once removed to the hospital. Under an anæsthetic a fine silver probe was easily passed straight into the brain substance for about an inch. It was withdrawn quite black. A grooved director was then passed in the same manner, when a gush of very fetid pus took place. The opening was carefully enlarged, the abscess cavity washed out with one to forty carbolic lotion, a drainage-tube inserted and left in. The direction of the sinus was downwards, backwards, and inwards. The drainage-tube was filled with carbolic lotion, which was seen to rise and fall with each pulsation of the brain. After the operation there was left-sided hemiplegia. Six hours after this the child had regained consciousness, and next day the hemiplegia had disappeared. The abscess was washed out daily through the drainage-tube which was shortened on the ninth and taken out on the fourteenth day. Patient was discharged perfectly well five weeks after the opening of the abscess. One month after discharge she was in usual health.

#### PROPAGATION OF MEASLES BY HEALTHY PERSONS.

FROM an editorial of *Le Concours Médical*, June 12, 1886, the *Therapeutic Gazette* (November 15) abstracts the following observations:

The possibility of carrying the contagious principle of measles from place to place by the medium of the bodies of healthy persons was recently discussed by the Medical Society of Berlin, and one gentleman, Joel, of Lausanne, presented certain facts which lead to the belief that such a possibility does exist, and that the medium is often furnished by the physicians themselves. One case which was cited was that of a boy who was brought from Geneva to Lausanne while he was passing through the incubation stage of measles. The butcher and the postman who served the institu-

#### CASE OF COMPOUND COMMUNUTED FRACTURE OF SKULL; HERNIA CEREBRI; ABSCCESS; RECOVERY.

DR. W. ODILLO MAHER, of Sidney, reports in the *Australasian Medical Gazette* for December, 1885, a most remarkable and interesting case of head injury, which is summarized in the *Edinburgh Medical Journal* (November, 1886). F. M., aged four and one-half years, fell off a balcony twelve feet on to asphalt. Unconscious when taken up; vomited blood; bleeding from nose; small lacerated wound on right frontal eminence; fracture of frontal bone; brain substance between edges of bone; wound dressed with iodoform and wool; mercurial purge ordered, head shaved, and

tion to which the boy was brought conveyed the disease to their children, who were attacked with it in a short space of time, and, what is quite remarkable, the children in almost every house to which the postman delivered letters were attacked. A little girl was brought to a hospital, and in a few days had undoubted symptoms of measles. Her father had paid her several visits before the measles appeared, and it was ascertained that two of his children were suffering at his home from the disease. Eight other children in the hospital were quickly seized with it.

It is thought that physicians cannot always avoid carrying the contagion with them, even when extraordinary care is taken. Prophylactic means on the part of the physician should be as thorough as possible, however, by disinfection, change of garments, and all other available procedures.

#### SPONTANEOUS RUPTURE OF THE UTERUS DURING PREGNANCY.

At a recent meeting of the London Medical Society (*Lancet*, November 13), Dr. A. H. N. Lewers read a paper on "Rupture of the Uterus during Gestation." It is an accident of rare occurrence, and its causation is but little understood. A study of nineteen recorded cases led Dr. Lewers to express the opinion that "spontaneous" rupture during pregnancy was in-

variably due to "interstitial" gestation. He described a case that occurred in his own practice at the London Hospital, in which a multipara, believed by herself to be in the fifth month of gestation, suddenly became ill with severe pain in the abdomen, vomiting, and collapse. Abdominal section was performed, and then the fetus and placenta were discovered in the peritoneal cavity, and a rent in the fundus of the uterus was detected at the outer part on the left side. The post-mortem examination showed that the rent in the uterus involved that part of the wall through which the left Fallopian tube passed. The case was not one, therefore, of genuine rupture of the uterus, for the fetus had never occupied the uterine cavity. Dr. Lewers considered that spontaneous ruptures of the uterus attributed to pathological softening of the wall were of doubtful occurrence. He thought, also, that cases of genuine spontaneous rupture should be kept apart, and not placed in the same category as those where rupture of the uterus occurred during premature labor, or in criminal attempts at the production of abortion, or from direct violence. There was nothing in the records of cases of spontaneous rupture to militate against the suggestion he desired to make—that spontaneous uterine ruptures are invariably cases of "interstitial" gestation. He submitted that where the symptoms pointed clearly to the occurrence of the accident, exploration of the abdomen was the correct surgical treatment.

#### REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 1, 1887.

Deaths reported 1,958: under five years of age 709; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 292; lung diseases 291, consumption 273, diphtheria and croup 109, measles 82, typhoid fever 29, diarrhoeal diseases 28, malarial fever 13, scarlet fever eight, cerebro-spinal meningitis seven, whooping-cough seven, erysipelas seven, puerperal fever two. From diarrhoeal diseases, New York 11, New Orleans eight, Boston four, Pittsburgh, Lowell, Worcester, New Bedford and Fitchburg one each. From malarial fever, New York six, New Orleans five, Baltimore and District of Columbia one each. From scarlet fever, New York and Philadelphia three each. Boston and Gloucester one each. From cerebro-spinal meningitis, New York, five, Fall River two. From whooping-cough, New York and Baltimore two each. Philadelphia, District of Columbia and Pittsburgh one each. From erysipelas, New York four, Pittsburgh three. From puerperal fever, Baltimore and Cambridge one each.

In the 20 cities and greater towns of Massachusetts, with a population of — (population of the State 1,941,465) the total death-rate for the week was 21.77 against 20.50 and 21.05 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,935,817, for the week ending December 18th the death-rate was 20.7. Deaths reported 3,605; infants under one year of age 813; acute diseases of the respiratory organs (London), 416; measles 141, scarlet fever 77, whooping-cough 54, diphtheria 37, diarrhoea 34, small-pox (London) one.

The death-rates ranged from 11.9 in Derby to 37.1 in Preston; Birmingham 17.1; Blackburn 25.9; Hull 18.8; Leeds 23.5; Leicester 25.8; Liverpool 27.6; London 18.8; Manchester 25.9; Newcastle-on-Tyne 24.6; Nottingham 18.5; Sheffield 17.1.

In Edinburgh 18.2; Glasgow 27.0; Dublin 29.6.

For the week ending December 18th, in the Swiss towns there were 38 deaths from consumption, lung diseases 31, diarrhoeal diseases 10, diphtheria and croup five, measles four, whooping-cough, typhoid fever and puerperal fever each one.

The death-rates were: at Zurich 13.4; Geneva 19.2; Basle 17.8; Berne 26.4.

The meteorological record for the week ending January 1, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending Saturday, Jan. 1, 1887.	Barom- eter.	Thermometer.		Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather.			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 1, 1887, TO JANUARY 7, 1887.

RAYMOND, H. I., first lieutenant and assistant surgeon. Ordered for duty at Presidio of San Francisco, Cal. S. O. 127, Department of California, December 29, 1886.

#### SOCIETY NOTICES.

SUFFOLK DISTRICT MEDICAL SOCIETY. OBSTETRIC AND GYNÆCOLOGICAL SECTION.—There will be a meeting of this Section at the large Medical Library Room, 19 Boylston Place, on Wednesday evening, January 19th, at 7.45 o'clock. Dr. J. S. Greene, of Dorchester, will report "Three Cases of Labor, two being Breech, and the other Arm Presentation, where the Legs were extended, and the Feet were near the Face." Dr. Edward Reynolds will report "A Case of Difficult Labor." Refreshments after the meeting.

JAMES R. CHADWICK, M.D., Chairman.  
ROBERT B. DIXON, M.D., Secretary.

MIDDLESEX SOUTH DISTRICT MEDICAL SOCIETY.—A regular meeting for medical improvement will be held at the Woodland Park Hotel, Auburndale, at 4 o'clock, P.M., on Wednesday, January 19th, 1887. Dr. T. H. Gage, President of the Massachusetts Medical Society, will read a paper on "Middlesex and Worcester Physicians of Ninety Years ago." Papers will be read on "Radical Gynecology," by Dr. E. D. Hooker; "Conservative Gynecology," by Dr. W. Preble. The discussion will be opened by Drs. A. Worcester and J. T. G. Nichols. Dr. F. E. Porter will report a case of clinical interest. Trains leave Boston and Albany Station in Boston at 3.05 and 3.45 o'clock, P.M., for Auburndale. Dinner at 6 o'clock, P.M. Telephone number of Hotel, 8101.

WALTER ELA, Secretary.

Is Tubercular Consumption Inherited? By H. D. Didama, M.D. Syracuse, N. Y. 1885.

A Contribution to the Study of Tumors of the Spinal Cord. By B. Sachs, M.D. 1886. (Reprint.)

A Skull of a Navajo Child. By R. W. Shufeldt, M.D., Captain Med. Corps, U. S. Army. 1886. (Reprint.)

The Infectious Diseases in their Relations to the Public Schools. By L. W. Baker, M.D., Baldwinville, Mass. (Reprint.)

Osteological Note upon the Young of Geococcyx Californianus. By R. W. Shufeldt, C.M.Z.S., Captain Med. Corps, U. S. Army. 1886. (Reprint.)

Thirty-first Annual Report of the Trustees of the Northampton Lunatic Hospital. For the Year ending September 30, 1886. Boston. 1887.

A Contribution to our Knowledge of Fever and of the Agents which produce or arrest it. By Drs. H. C. Wood, E. T. Reichert, and Hobart A. Hare. Detroit, Mich. 1886.

Pleurotomy for Empyema: Recovery. By F. C. Fernald, M.D. (Harvard), of Washington, D.C. Read before the Medical Society of the District of Columbia, on October 20, 1886. Chicago, 1886. (Reprint.)

Årsberättelse (den Sjunde) Fran Sabbatsbergs Sjukhus i Stockholm. For 1885. Afgifven af Dr. F. W. Warfvinge, Sjukhusets Direktör och Överläkare vid dess medicinska afdelning. Stockholm. 1886.

The Social Waste of a Great City. A Paper read before the American Association for the Advancement of Science, at its Annual Meeting in Buffalo, August 20, 1886. By Louis L. Seaman, M.D., LL.B., Late Chief of Staff Charity, Maternity, Penitentiary, Epileptic, and Paralytic Hospitals, B. I.; Member of the A.A.A.S. New York. 1886. (Reprint.)

## Original Articles.

THE AMBLYOPIA OF SQUINT.<sup>1</sup>

BY O. F. WADSWORTH, M.D.

THE theory that the amblyopia so prevalent in strabismus is the result of a suppression of the image formed in the squinting eye, in order to avoid the confusion excited by double vision, was for a long time universally accepted and was upheld by the authority of the leaders in ophthalmology. This amblyopia was regarded as a form by itself and given the name of *amblyopia ex anopsia*.

Schweigger, in his handbook, published in 1871, denied that the amblyopia is so produced, and asserted that it is on the contrary a congenital defect; and Alfred Graefe, in 1875,<sup>2</sup> retracted the opinions he had formerly expressed, and gave in his adhesion to Schweigger's views.

By the early part of 1876, I had, from observations made during the previous few years, convinced myself that *amblyopia ex anopsia*, so called, did not exist, and believed at first that I was alone in this conviction. Examination of the literature of the subject, preparatory to a paper, showed me that Schweigger and Graefe had preceded me, and had presented the matter so much more fully and so much better than I could hope to do with my limited material that I immediately abandoned the idea of writing.

A little later, in 1877, Leber<sup>3</sup> strongly upheld *amblyopia ex anopsia* against the assaults of Schweigger and Graefe, without, however, presenting anything new.

Again, in 1881, Schweigger published a masterly monograph on strabismus, based on the observation and statistics of a large number of cases, in the course of which he argued more at length against the suppression-amblyopia theory.

If I now, at this late date, bring the subject to your attention, it is because what I regard as an erroneous doctrine still is widely prevalent, and is taught by most of the recent text-books. At the last meeting of the American Ophthalmological Society Dr. Theobald read a paper in its support.

Before going farther, it should be said that, in many cases, opacities of cornea, lens or vitreous, or changes in the fundus, sufficient to account for the amblyopia present, are found in the squinting eye. With such cases as these the discussion need not concern itself.

The importance of the question is not merely theoretical. If *amblyopia ex anopsia* is a fact the practical treatment of squint should be greatly influenced by it. If a squint persisting for a few months, as some of the advocates of the doctrine assert, is sufficient to bring about a pronounced and permanent defect of vision in the squinting eye, it should be our duty in all cases to operate for its removal as early as possible. In all cases, at least, in which no visible lesions, ample of themselves to prevent a useful amount of vision, are present. If, on the other hand, persistence of the squint does not cause amblyopia, we may postpone operation with advantage till such time as it is possible to determine any errors of refraction that may exist, and, by correcting these

errors by appropriate glasses, assist the effect of the operation. That errors of refraction do exist in a large majority of cases every one admits.

The chief hindrance to a decision of the question which shall be generally accepted is the fact that at the early age at which strabismus usually begins (two to four years) it is in most cases impossible to obtain any satisfactory evidence as to the amount of vision; and, on the supposition that a few months of squint are enough to cause a decided loss of sight, by the time the child is of an age to admit the application of convincing tests it is too late to settle the dispute as to whether a defect then discovered is congenital or acquired. Again, if when the tests can be made no defect be found, as not seldom happens, the advocates of *amblyopia ex anopsia* claim that this is accounted for by the circumstance that the squint has not been monolateral, that sometimes the habitually deviating eye has been used, and there has been therefore no continuous suppression.

On the other hand, it is to be said that no satisfactory evidence of deterioration of vision in a good eye after squint has appeared has been presented. Theobald<sup>4</sup> says of this, "that there are scores of cases recorded in the note-books of ophthalmic surgeons in which there has been observed a progressive decline in the vision of squinting eyes, I do not for a moment doubt." That he has record of none such himself is evident. But he cites Roosa<sup>5</sup> as reporting one case of this character. Roosa<sup>5</sup> gives this case, in which the records of vision were made at an interval of four years by two different assistants, as "the only case that I have personally seen, where any color is given to the theory of amblyopia, or deterioration of vision from disuse of the eye." But he also states that the results of the analysis of all his cases give no support to the *amblyopia ex anopsia* theory.

Even one case carefully observed deserves respectful consideration. But in the case here quoted there is not, it seems to me, sufficient guarantee against possible mistake. And the mistake may have occurred in either of two directions; the first observer may have overestimated the vision of the squinting eye, or the second observer underestimated it. Any one who has had much experience in testing vision must have recognized the liability to error in the examination of young children, and this liability is decidedly increased when we have to do with a squinting eye.

Let me illustrate. A child of some nine years of age with convergent strabismus was examined by my assistant. The letters of XX were read at 20' first by the non-squinting, then by the squinting eye, thus apparently showing V. =  $\frac{3}{8}$  in each. Then, at my suggestion, all the letters of XX were read backward, without mistake, by the squinting eye. Yet on covering the test card so that only one letter could be seen at a time, letters of XL were the smallest that this eye could recognize. Its vision was, in fact, only  $\frac{3}{8}$ . The letters had been unconsciously committed to memory when they were read by the good eye. Here, if the examination had been pushed less far we should have overestimated the vision, and a few years later re-examination might have shown progressive deterioration of vision in a squinting eye.

Another example demonstrates how vision may be underestimated at a subsequent examination. A girl

of six years, with marked convergence of the left eye since the age of two and one-half. Under the influence of duboisia, V. =  $\frac{1}{16}$  in each eye. The test was made with every precaution, the non-deviating eye being effectively bandaged, and a card taken for the testing of the squinting eye which the child had never before seen. Tenotomy of left internus under ether, with decrease, but not correction of the convergence. Eight months later the best vision that I could get was R.  $\frac{1}{16}$ , L.  $\frac{1}{16}$ . There was apparently decided diminution of vision in both eyes, greater in the squinting eye. The child was of a very nervous temperament, and after the tenotomy always became excited whenever a visit to me was suggested. I entertain no doubt that the deficiency of vision found at the later test was due to the mental disturbance and excitement which then existed.

Even in adults it is by no means always easy to determine accurately the amount of vision. A lady of forty-two years had had a strong convergent squint of the right eye since the age of nine. She had been an invalid for a long time. On repeated examination on different days, both without and with atropine, the best vision obtained was R.  $\frac{1}{16}$  —, L.  $\frac{1}{16}$  —. Seven months later, her general health having meanwhile improved, but the squint remaining the same, there was found R. V. =  $\frac{1}{16}$ , L. V. =  $\frac{1}{16}$ .

The two main arguments on which the supporters of acquired amblyopia rely are, (1) the peculiar character of the defect of vision, (2) the asserted fact that a visual defect of like character is rarely if ever found without squint.

Let me state their thesis. The peculiarity of the amblyopia consists in this: with no visible change in the eye, a perfectly normal appearance of the fundus, and without any narrowing of the boundary of the visual field, there is impaired function of the region of the macula and all those parts of the retina which receive images of objects situated in the common visual field.

In order to avoid the bewilderment caused by the double images which are induced by the faulty direction of the squinting eye, the impressions received through it are persistently suppressed, and the attention is concentrated on the impressions received through the other. The process is the same as when we apply one eye to the microscope or ophthalmoscope and, keeping the other open neglect the images formed on its retina. In strabismus, however, the suppression of the images is not merely temporary, but continuous, and causes a blunting of the function of the retina or of the corresponding visual centres in the brain. Only the peripheral portion of the nasal half of the retina, not being concerned with the common visual field, is exempt from this influence and unaffected.

At the early age at which squint generally begins a few months of suppression may be enough to produce a high degree of amblyopia, yet the longer the suppression has persisted the greater is the deterioration of sight. Theobald<sup>6</sup> assents to this last as a rule, but assumes that structural changes take place in the visual centres,<sup>7</sup> and that when the suppression "has produced such a degree and such a kind of amblyopia as shall do away with the discomforts of double vision, its purpose is accomplished, and it probably ceases to be operative."

<sup>6</sup> Loc. cit., p. 281.

<sup>7</sup> Loc. cit., p. 283.

In alternating strabismus the suppression is not constant, and therefore amblyopia does not result.

This is, I believe, a fair statement of the theory. How is it borne out by the facts? If it be true, then the amount of amblyopia found in squinting eyes should be approximately the same, or, if the element of time is to be considered, its degree should show some correspondence with the length of time the deviation has existed. No one has ventured to offer an estimate of the least amount of amblyopia that is capable of satisfying the suppression theory.

Schweigger<sup>8</sup> has given statistics of the refraction and vision of several hundred cases of strabismus. He found vision less than  $\frac{1}{4}$  in about 30 % of the squinting eyes, but makes no subdivision between normal vision and V. =  $\frac{1}{4}$ .

Hospital cases, treated as out-patients as they generally are, rarely are recorded or examined with sufficient accuracy of detail to furnish available statistics.

I have taken the cases of strabismus occurring in the records of my private practice. All those in which changes in the fundus, or opacities of the media, might account for the defective sight, and all in which the youth of the patient or other cause prevented the determination of the vision and satisfactory examination of the retina have been thrown out as useless for the purpose in hand. With this exception only, four cases in which the vision of each eye was recorded, but there was no note as to the fundus, have been included, but in each of these the vision of the two eyes was nearly alike and fairly good,  $\frac{1}{16}$  to  $\frac{1}{8}$ .

There remained 57 cases of convergent strabismus.

Five of these had divergence when they came to me: 4 following operation for convergence; 1, at 23, M.  $\frac{1}{16}$  and V. =  $\frac{1}{16}$  in one eye, H.  $\frac{1}{16}$  and V. =  $\frac{1}{16}$  in the other, had changed spontaneously from convergence. Three were nearly or quite straight, after tenotomy. Five were alternate, 4 periodic, 47 monolateral.

In 15 cases (26 %) (4 alternate, 1 periodic) V. was precisely the same in each eye; in 7 of these (2 alternate, 1 periodic) V. =  $\frac{1}{16}$  to  $\frac{1}{8}$ .

In 9 cases (16 %) (1 alternate) the difference between the vision in the two eyes was not greater than that between  $\frac{1}{16}$  and  $\frac{1}{8}$ .

The poorest V. in these 24 cases was in a case of M. with slight nystagmus, R. —  $\frac{1}{16}$ , V. =  $\frac{1}{16}$ , L. —  $\frac{1}{16}$  —  $\frac{1}{16}$  cyl., V. =  $\frac{1}{16}$ .

Of the remaining 33 cases, V. in the squinting eye was:  $\frac{1}{16}$  to  $\frac{1}{8}$  7 (12 %):  $\frac{1}{8}$  to  $\frac{1}{4}$  8 (14 %):  $\frac{1}{4}$  to  $\frac{1}{2}$  7 (12 %) (3 periodic):  $< \frac{1}{16}$  to counting fingers at 15" 11 (20 %).

The poorest V. in the non-squinting eye was  $\frac{1}{16}$ .

The same selection as before gave 11 cases of divergent strabismus: 1 alternate, 2 periodic, 8 monolateral.

In 5 (45 %) (1 alternate, 2 periodic) V. was alike in the two eyes,  $\frac{1}{16}$  to  $\frac{1}{8}$ .

Of the other 6 cases, V. in the squinting eye was:  $\frac{1}{16}$  to  $\frac{1}{8}$  2 (18 %):  $\frac{1}{8}$  to  $\frac{1}{4}$  2 (18 %):  $\frac{1}{4}$  to  $\frac{1}{2}$  1 (9 %): fingers 5' 1 (9 %): both the last two cases having As.  $\frac{1}{2}$  with ophthalmoscope.

Lowest V. in non-squinting eye  $\frac{1}{16}$  —  $\frac{1}{8}$ , with M.  $\frac{1}{16}$ .

Uniting all the cases they give 30 % with V.  $< \frac{1}{4}$

<sup>8</sup> Klinische Untersuchungen ueber das Schielen. Berlin, 1881.

( $\frac{1}{16}$ ), practically the same percentage as found in Schweigger's much more extensive statistics.

These cases are not numerous, but I believe they are fairly reliable. The only error probable is that in a few the full amount of vision may not have been obtained; certainly it was not over-estimated.

The statistics here given seem to offer little encouragement to the theory of *amblyopia ex anopsia*. Half the patients had in the squinting eye V. at least  $\frac{1}{16}$  to  $\frac{1}{8}$ , leaving out of the calculation two with vision somewhat less than this, but alike or nearly alike in both eyes. It is certainly common enough to find vision as low as  $\frac{1}{16}$  in eyes without squint and without visible change; more than half the cases then must be considered to have escaped the evils of suppression.

It is said, however, that the instances in which vision is not greatly decreased may be easily explained on the supposition of an occasional alternation, that this is sufficient to preserve the function intact. I can hardly believe it has been expected that this supposition should account for some half of the cases. If the explanation be admitted, how shall we account for the fact that in three of my patients the eyes were sometimes straight, both by the statement of parents and by my own observation, and yet vision was only  $\frac{1}{16}$  to  $\frac{1}{8}$  in one eye. All the three had like refraction in the two eyes (two hypermetropic, one emmetropic), all measured with the ophthalmoscope as well as with glasses, two under homatropine. The emmetrope, a boy of seven years, had, three years earlier, before he knew his letters, evidently imperfect sight of one eye.

It is asserted also that a difference in the refraction, by causing the images formed on one retina to be indistinct, facilitates suppression. This may be fully granted without at all helping the theory. The question is not whether there is suppression, suppression of some sort there must be else we should have double vision, but whether the suppression causes amblyopia.

On the other hand, Theobald brings forward differences of refraction as a hindrance to amblyopia. He says, "the non-development of amblyopia in exceptional instances is easily explained without the necessity of abandoning the suppression theory, a marked difference in the refraction of the eyes being competent to produce this result, because the indistinct retinal image which the squinting eye receives under such circumstances causes less confusion and is, therefore, less apt to be suppressed."

Both views can hardly be true. With regard to the latter one, four of my cases with monocular amblyopia (V. =  $\frac{1}{16}$  to counting fingers at 2') had, three of them As.  $\frac{1}{2}$  to  $\frac{1}{4}$ , the fourth a high degree of myopia and As. in the squinting eye, measured with the ophthalmoscope. The marked difference in the refraction did not protect here. Nor did it protect in a fifth case with M.  $\frac{1}{16}$  and V. =  $\frac{1}{8}$  in one eye, H.  $\frac{1}{8}$  and V. =  $\frac{1}{8}$  in the other.

Another supposition of Theobald, already quoted, that the suppression probably ceases to be operative when it has produced a certain degree and kind of amblyopia, accords poorly with the great variability in the amount of the visual defect which the statistics have shown.

To answer the second argument, that monocular amblyopia without visible change is rarely if ever

found in non-squinting eyes, I refer again to my records. The indexes of my case books do not make the selection of these cases so easy as those of strabismus, yet I have readily found 15 cases, in which the eyes were perfectly normal in appearance, which had never squinted, but had monocular amblyopia ranging from V. =  $\frac{1}{16}$  to  $\frac{1}{8}$ , five of them with V. <  $\frac{1}{8}$ . The vision of the better eye was in only one of the fifteen cases so low as  $\frac{1}{16}$ , in one other so low as  $\frac{1}{8}$ ; while of the five cases with V. <  $\frac{1}{8}$ , in but one had the better eye so little vision as  $\frac{1}{16}$ .

Moreover, I have excluded from this series cases with excessive degrees of H. or M., or with more than the lowest degrees of astigmatism, to avoid the possible objection that the amblyopia was due to the same faulty development which caused the refractive error. Had such cases been admitted the list could have been easily extended, and it is to be noted that several such cases are found among the amblyopic squinting eyes.

Further, squint is a personal blemish, patent to all observers, and naturally sends the patient to the physician; congenital monocular amblyopia is not apparent, is often neglected, often discovered only accidentally and late in life.

A man of fifty-one years came to me because he had, two or three weeks before, accidentally found his right eye imperfect. Both eyes were quite normal in appearance, externally and internally. R. V. =  $\frac{1}{16}$ ; L. V. =  $\frac{1}{8}$ ; H.  $\frac{1}{8}$  in both. On inquiry, I learned that as a boy he had used the left eye in shooting, because, as he said, "I could never close the left eye well and see well with the right." Yet only lately had he realized that the right eye had imperfect sight.

The second argument, then, is evidently based on faulty or limited observation. Nor need it weaken the force of this statement if monocular amblyopia is found in larger proportion among those who squint than among those who do not. Donders,<sup>10</sup> at the same time that he pointed out the influence of hypermetropia in convergent squint, also showed that imperfection of vision in one eye rendered the occurrence of squint more easy.

One other argument needs to be noticed: It has been frequently claimed that a marked improvement in the sight of the squinting eye often occurs immediately, or in a short time after it has been straightened by tenotomy, and this asserted fact has been adduced as evidence that the amblyopia could not have been congenital.

Perhaps the extravagance to which this claim has been pushed never reached a greater height than when, two or three years ago, an oculist reported a case in which, as he asserted, the squinting eye had not even perception of light, but after it had been straightened by operation, acquired by exercise a considerable amount of vision.

Leber<sup>11</sup> states: "In the lesser degrees of amblyopia from disuse, where central vision has not yet been wholly lost, great improvement or complete restoration may be effected by practice"; and on the following page: "Very remarkable are the cases where tenotomy brings about an immediate improvement of a very high degree of amblyopia, which, therefore, certainly must have been caused and maintained by the squint—cases which still need an explanation."

<sup>10</sup> "On the Anomalies of Refraction and Accommodation of the Eye," p. 295, 296. London, 1864.

<sup>11</sup> Loc. cit., p. 1014.

<sup>9</sup> Loc. cit., p. 281.

He gives as an example a case reported by Knapp<sup>12</sup> in 1863, in which, directly after operation, vision was said to have risen from  $\frac{1}{4}$  to  $\frac{1}{2}$ . Then, after some further discussion of these cases, he goes on to say: "Sometimes, also, the strabismics find the right use of their eyes even before the tenotomy; I have seen cases in which, during my testing, the at first greatly reduced vision, within a few moments improved almost as remarkably as in the above-mentioned case after the squint operation." The hollowness of the evidence that straightening the eye causes an increase in its vision could hardly, I think, be better illustrated.

One would think that such experience as this would have awakened attention to the liability of mistake, and the necessity of careful and repeated testing of the squinting eye before deciding on its actual amount of vision, or assuming an improvement from the operation. Leber seems, indeed, to have had some inkling that the unaccustomed strain on the muscles needed to bring the squinting eye into correct fixation may have interfered with the proper concentration of the attention on the visual act. But it evidently did not occur to him that the theory of amblyopia from suppression demands a continuous, not an intermittent amblyopia; not an amblyopia which is present only so long as the attention of the squinter is absorbed by something other than the letters which he is called on to read.

This experience of Leber offers a key to the whole matter, not simply that an unaccustomed strain on the muscles accompanies the attempt to see—that is only one of the factors involved—but the secret of the apparent improvement observed after tenotomy is found in the lack of sufficiently careful previous examination. When vision has been exhaustively tested before tenotomy, no real improvement is found after it.

The facts, that a not inconsiderable proportion of strabismics have vision alike or nearly alike in the two eyes even when, according to all the evidence attainable, the squint is strictly monolateral; that in a consideration standard; that only about 30 % of squintable number of other cases the amblyopia of the squinting eye is not of high degree, while in some of these vision of the non-squinting eye is also below the normal, among them many with high degrees of astigmatism or other refractive error, have vision less than  $\frac{1}{2}$ ; and finally, that there are many persons with congenital monocular amblyopia of equally high degree who do not and never have squinted, make it a reasonable requirement that, before the theory of suppression-amblyopia be accepted, some positive evidence of its existence, something more than a mere hypothesis, should be brought forward to support it.

There is, however, a condition of functional disability often found in squinting eyes which is dependent on the squint, and is in many cases capable of remedy. But it is not by any means peculiar to squint; it is not necessarily accompanied by a reduced acuteness of vision; correction of the deviation is not required for its removal; and when it is removed, acuteness of vision is no greater than it was before.

It consists in an incapacity for continuous use of the amount of vision which the eye possesses, and is due to long-continued want of exercise of the function. It may be overcome by separate practice of the eye. It is found also without squint when one eye has such an error of refraction that at all times very indistinct images are formed upon its retina. Such an eye may

take part in binocular vision to a certain extent, and aid in the estimation of distance; but if its error of refraction be corrected and it be called on to read it will give out speedily, yet, with practice, it may learn to read fluently and continuously. Clearly, this condition is widely different from that which has been described as amblyopia from suppression.

#### SOME CASES OF ALTERNATING INSANITY WITH ONE CASE OF RECOVERY.

BY EDWARD R. LANE, M.D.,  
Assistant Superintendent, Boston Lunatic Hospital.

BETWEEN the years 1851 and 1854, Falret and Baillarger, two French alienists, described independently of one another, a class of cases of an interesting form of insanity.

In these cases the opposite conditions of mania and melancholia or of excitement and depression succeeded each other with a certain amount of regularity.

To this form of insanity Falret gave the name of *Folie Circulaire*; while Baillarger, his rival for scientific honors, called it *Folie à double forme*.

The two names mean essentially the same thing, although certain later writers, anxious to recognize the claims of each observer, have tried to make a subdivision in the cases of alternating insanity, giving to two distinct groups the names of *Folie Circulaire* and *Folie à double forme*, but they have not been successful.

The disease *Folie Circulaire* as described by the French authorities mentioned, and later writers, is characterized as follows:

Periods of mania, depression and sanity follow each other with a certain amount of regularity, either in the order named, or the mania may follow the depression. In a certain number of cases there is no sane period. There may be the greatest variety in the length of the periods, although in a given case there is a certain amount of uniformity in the length of each cycle. Both the mania and the melancholia seen in this disease are described as having a peculiar phase of their own.

The mania is not accompanied with delirium, the intellect is not impaired. There is rather great exhilaration and activity, both mental and physical, with a perversion of the moral sense; in short, the condition described by the French as *folie raisonnée*.

The melancholia, on the other hand, is a stuporous condition, rather than a condition of great mental pain. The organic functions are impaired and the bodily condition is the reverse of that of the excited stage.

The depression usually lasts longer than the excitement, which it usually follows. During the excitement there is seen increased sexual feeling. There is a hereditary tendency in the majority of cases.

The disease does not tend to progress to dementia. The prognosis is highly unfavorable so far as a cure goes. It is not believed that life is shortened by the disease.

The cases here reported have seemed to me to belong to the group of cases described as *folie circulaire* and are interesting as showing the great variety

<sup>12</sup> Monatsbl. für Augenheilk., I, 474-478.

<sup>1</sup> Read before the Boston Medico-Psychological Society, October 21, 1886.

in individual cases of mental disease, and in their variations from what may be called the typical cases.

The first case I shall read I have ventured to call one of recovery. I cannot hope that the patient will go through life with no more mental trouble, as I believe the disease to be essentially one of degeneration, but as recoveries in mental disease go this seems like one.

CASE I. Miss M. E. C., born in Boston of Irish parentage. No insanity known in the family. Her mother is subject to asthma. Was considered a bright scholar until twelve years of age. She then began to have severe headaches, which so interfered with her school work that she was unable to keep up with her class.

Two years later she became subject to periods of depression (especially at the menstrual period) lasting about a week. She continued in this way, living at home, until twenty-two years of age.

At this time, during a period of depression she became excited. Delusions of persecution were active. She refused all food and nearly starved herself. She was so much frightened and so troublesome as to require constant attention from one of the family. In this condition she was committed to the Boston Lunatic Hospital, in June, 1883.

On admission to the hospital she was very weak, frightened and incoherent. Pulse 120. She required feeding with the tube for the next two weeks. She then began, gradually, to eat. Both feet swelled, left more than the right, during the first month in the hospital. She was noisy at times.

In August, having gained physically, she was allowed to dress. She was still very wretched and incoherent. She now gradually improved so that by October, ceasing to wet herself and being more rational, she was removed to a better ward. She would stand about, however, and for six months after admission, very strongly objected to lying in bed or sitting.

In December she stood less and became much brighter and asked for a library book.

For months she had been in the habit of standing near another patient of the same age who was dull, depressed, and stood most of the time; moreover, she still seemed much affected by this patient and would imitate her in many things.

For two weeks she continued bright and read novels, yet she seemed timid.

December 28th. She relapsed into the depressed condition, crying for fear something had happened at home. She again refused to stay in bed, and was in the same condition as before. With the exception of a slight remission of symptoms, lasting three or four days, the depression continued three and one-half months.

In April, she again became rational and cheerful. This had been preceded by a condition of increased activity, the patient being so troublesome and untidy as to be sent to the excited ward.

From this time the conditions of depression and exhilaration alternated for a year with fair regularity. Twelve cycles occurred in two hundred and sixty-four days, an average of twenty-two days. They were never under seventeen, nor over thirty days. The depression lasted twice as long as the exhilaration.

When depressed, she was extremely dull, and would

cry if spoken to, however kindly. She would stand in the middle of the floor for many hours, turning about as though on a pivot, wringing her hands. She seemed very wretched; she declined food and medicine. She was very obstinate. Her hands and face were blue and cold.

The change to exhilaration took place within twelve hours. The first sign of a change was the inclination of the patient to laugh. She would laugh in a silly way without cause. She would soon begin to steal. When excited, she always stole stockings and underwear of other patients, especially during the first part of the excitement. She showed considerable activity, and reached the height of her exhilaration on the second day. When accused of stealing, she would invariably lie about it. The exhilaration subsided considerably, and the patient became less troublesome before the period of depression. The nearest approach to sanity was at this time, yet there was no distinct period of sanity.

The last two periods of depression were somewhat different from the others — so much so, that the attendant remarked upon it. The patient was hysterical, laughing and crying in rapid succession. For hours she would make a low, hissing noise. At this time she saw her brother, but would give him no evidence of recognition.

A week later, when no longer depressed, she talked freely about the way in which she had treated her brother, and how badly he felt. She expressed no sorrow for her conduct, but related it as a fact of scientific interest.

Just before one of the later periods of depression, she remarked that she supposed she must be sick again, but she dreaded it. This showed more reasoning power than usual for her when exhilarated.

February 1, 1885. The depression gave way to the usual exhilarated condition. The exhilaration continued for four weeks, when, much to every one's surprise, the customary depression did not appear. The patient became more quiet, cheerful, and rational. She was more industrious, gained flesh, and showed an appreciation of affairs that had been quite foreign to her. She was ambitious to go home. She wrote thoughtful and sensible letters. In a little less than four months from the recovery from her last attack of depression, she was allowed to go home.

It is worth mentioning that menstruation ceased at the time of her coming to the hospital. It was renewed (and was afterwards regular) in June, 1884, two months after the alternation was established, and eight months before recovery.

She was seen October 15th, 1886, by the writer, and she seemed rational, talked sensibly on many subjects, and reported that she had been free from any depression or undue excitement. Her aunt corroborated her statement. This was twenty-one months after the last attack of depression. She is childish in some respects, laughs easily, and does not appear as other young women of her age who have been in society all their lives. This is very natural when it is considered that for ten years she was shut out from the world, and was unable to learn the thousands of little things a girl learns from fourteen to twenty-four.

CASE II. Mr. K., born in Maine in 1810, of Irish parents; sailor. No insanity known in the family. In 1845, at the age of thirty-five, he was admitted to the McLean Asylum. Through the courtesy of the officers

of that hospital, I am able to give the following concise history of the early symptoms in the case:

July 1st, 1845. He complained of a severe headache, with a rushing of blood to the head, for which he was freely bled and leeches, but without any permanent relief.

On the night of the 4th of July, he went with his wife to see the fireworks on Boston Common, where he appeared odd, and talked a great deal. He flourished his cane, and made singular remarks about the fireworks.

That night he awoke screaming loudly, and was much disturbed and confused. Had an impression that some one was after him. He was all right the next morning, however. For the next two weeks there was scarcely a day that he did not show, at some time, a certain amount of excitement.

On the 15th he became highly excited, and was removed to the jail. The following day he was admitted to the McLean Asylum, walking there quietly with his wife. He was aware something was wrong with his head, and he was willing to stay.

The clinical record is as follows: 17th. Quiet until afternoon. Grew excited and noisy. Moved to the middle story. Did not sleep. 18th. Restless all night and some noisy. After noon became very excited and noisy, pounded the door and screamed and was removed from the ward. Continued very noisy and violent and was removed still further. Thought his wife had been there and he was to be robbed and injured.

August 7th. Had frequent turns of being excited and became so noisy as to be sent to the lower ward. His more rational intervals are less distinctly marked and he does not seem to have so clear an idea of himself as when he first came. 18th. Discharged well.

From this account it does not appear how this attack could be distinguished from an ordinary attack of acute mania.

A detailed account of the succeeding history of the case would fill a good-sized volume and only a general account of the case can be given. A chart has been prepared to show the time and relative length of the different periods of excitement, depression and sanity. The chart cannot be given here. On it was a record of thirty-three attacks of mania and eighteen attacks of depression; sixteen of the attacks of mania began in the three months, November, December and January; eight in December. Four attacks of depression began in December. Previous to 1865 there is little clinical history obtainable, and I have assumed that certain times spent in hospitals were periods of excitement. From 1845 to 1869 he was sent to a hospital eighteen times. Two commitments, however, are for one attack. He may have had slight periods of excitement for which he was not sent to a hospital, but it is now impossible to ascertain if such was the fact.

For many years there have been noticed two distinct degrees of excitement. For a short time there would be great excitement. The patient would destroy his clothing and bedding, daub himself and the room with filth, and be extremely noisy. This condition usually ushered in the excited stage. Occasionally, however, there would be two or three outbursts of excitement during the period of exhilaration.

The excitement usually begins suddenly. For the past fifteen years the most sudden changes in the patient's condition would be those from depression to

great excitement. Sometimes this change would take place within twenty-four hours. Usually not more than three days were needed to reach the highly excited condition.

For a great many years it has been an invariable custom with this patient just before the onset of an excited period to shake hands with the right index finger stiff.

When becoming excited he also has a habit of mixing all his food in one mess. Bread, coffee, soup, meat and sauce are stirred together. Clouston mentions a case who had the same habit.

When excited he is full of bluster and braggadocio, is very noisy and profane. He demands certain privileges as tobacco, his discharge, etc., in a loud tone, and makes severe threats with many oaths if he is not given all he asks. He is usually good-natured, but is at times cross and sullen. Does not treat his wife as well as he does other people. He does not seem to have been as cross in later years. Although he will flourish his fists, square off, and threaten to take possession of the ward he is seldom violent.

This patient when excited is always very busy with his clothing. He sews it and tears it, always dressing fantastically, and making a very amusing spectacle of himself. There is nothing more characteristic of his excitement than this constant tearing and sewing.

In the earlier years of hospital life he would always succeed by fair means or foul in getting hold of a needle and thread and proceed to patch his clothes with a piece of carpet or bed-ticking. He would sew the sleeves of his coat or he would quilt the entire suit. He was also fond of braiding straw, making himself a hat. During the height of his excitement he would tear all his clothing to strips and decorate himself with a few narrow bandages. The record mentions him at one time as being very happy and stark naked except for a string tied about his penis.

In later years has not been so thoroughly destructive, but he tears parts of his clothing to strings and then makes knots in the strings.

He was given a strong suit a few years ago and it seemed to annoy him because he could not tear it. One morning he was found to be quite contented, and on examination it was found he had secured a bit of glass and punched a hole in his coat and tied two strings through the hole.

His conduct at these times is thoroughly lawless, he is forgetful of all the proprieties. He will even swear at others for indulging in profanity. As the excitement subsides he is seen to have a good memory and be very witty. He cannot be made to stick to one subject long enough to test his general knowledge.

He is full of pranks, and occasionally gets into trouble. One of the most narrow escapes was forty years ago, at the beginning of an excited spell, when he flourished two horse pistols about considerably, much to the alarm of his friends. He proceeded with them to the Navy Yard, where he was employed, and fired into a Chinese junk then visiting this port, saying that curiosity had no business here. At this same time he threw cold water over his wife and daughter, to make them smarter.

The depressed periods come on slowly. At first they were not over a month in duration. There is no record of when they first came on, but it is mentioned, in 1870, that they had been formerly an invariable sign of recovery.

The length of the depressed period has steadily in-

creased, until it is now from ten to sixteen weeks. There is considerable inertia, loss of appetite, and general physical depression. The face and hands are blue and cold. At these times the patient always complains of "rheumatism," saying his bones ache. Often the recovery from this period is gradual, but the succeeding condition is invariably one of great excitement.

Since 1869, the average length of the depression has been seven weeks, that of the excitement six and one-half months, making the average for the whole cycle a little over eight months. During the first twenty years of the disease, there was a distinct period of sanity following the depression. For the last twenty years there has been no sane interval, not even a vestige of it after the depression.

CASE III. Mr. B., American, born in 1828, merchant; married; no heredity. In 1871, at the age of forty-three, he suddenly became excited. The attack came on in the night, and was preceded by severe headache frontal and occipital. Was afraid he was going to die; was excited and extravagant, buying a horse and buggy while away from home. His excitement lasted a month, which time he spent in New York. Five years later he had another slight attack. In the meantime he had lost all his property in the Boston fire, and was not disturbed mentally by his losses.

In the spring of 1882, six years later, he was overworked. As in the first attack, he was awakened at midnight by severe pain in the head. This time he went South. He bought three guns for himself and chance acquaintances, intending to make a hunting expedition, but he suddenly changed his plan, and wanted to help all churches, bought fireworks, and "treated" liberally, spending money very freely: He returned home prostrated. This attack lasted about a month. The fourth attack of excitement was preceded by business trouble, and came on in August, 1883. The patient went to New York, where he consulted a specialist in nervous diseases. The following night he was disturbed, and called a doctor in the night. As usual, he began to make extravagant negotiations. This time he planned a trip to Fayal. Was treated for four weeks in the Boston Lunatic Hospital; was extremely excited, destructive, and violent.

Since the fourth attack he has had a period of mild depression each winter. It is not stated whether he was subject to depressed periods before this. In one of these depressed periods he joined the church. In the summer of 1884 he was exhilarated again, but did not require hospital treatment. The following winter he was somewhat depressed, with no known cause.

In July, 1885, he had the sixth attack of mania. For a few days only was he violent or destructive, and even then he manifested a strong desire to control himself. This attack lasted a month. Running over with good nature, and extremely restless, talking constantly, and writing numerous letters, he made it very lively for all about him. He made many witty remarks, and told a great many stories. His extreme restlessness and activity, with a tendency to extravagance, were the characteristic symptoms of this attack of mania. There was little, if any, of the moral laxness characteristic of the exhilaration of *folie circulaire*. The extreme excitement did not appear until he had been in the hospital a week. For two days he tore his clothing, struck other patients, and tried to escape.

CASE IV. Mrs. R. F. B., American, born in 1837.

No insanity in family. Mother had facial paralysis at time of patient's birth; no intemperance in family. No known cause. At nineteen years of age had an attack of "hysteria," and was treated in a water-cure establishment. Was excited, talkative, violent, and required restraint. Three years later she had the next attack of excitement. In the meantime she had married. For the first six or seven attacks she was kept at home. After that she was sent to hospitals.

In thirty years she had twelve attacks of excitement, lasting four to five weeks, followed by a period of mild depression, lasting about the same time. This was succeeded by a period of sanity lasting from eighteen months to three years.

The excitement comes on suddenly. She cries out in the night, and complains of a distressed feeling and pain in the head. When excited, she mixes up her food, ties knots in her clothing, dresses fantastically, and is very busy cleaning and arranging her things.

When depressed, is dull and inactive, regrets her extravagance when excited, and distrusts her ability to get along without hospital restraint. Once a temporary attack of excitement and depression was caused by the annoyance of moving. The whole attack was shorter and milder than usual.

During the excitement, which the writer witnessed, the patient was very talkative, but coherent, and indulged in profanity. She would talk for hours on family affairs, and describe details of unimportant matters with painful accuracy. For many days she did not get dressed until afternoon, saying she was too busy to dress. She would busy herself cleaning the room, washing the furniture, shaking and turning the mattresses. She was continually slopping water about and making great confusion. She would mix her food, and at times would spend three hours eating a small meal.

She amused some and shocked others by making a catafalque of a black shawl and a bed, in honor of General Hancock. She would play the piano for old patients to dance.

During the excitement she was very familiar, and made many personal remarks. She would appropriate anything she liked, and then give it to any one she chose. She filled a bureau-drawer with purloined articles, and then denied ever having them. Although rough, she was seldom violent. One evening she screamed for hours to spite some one who had annoyed her. Her conversation was inclined to be broad unless she were checked.

She menstruated during the excitement, and at this time she said and did some coarse things. The excitement continued for five weeks. After this, for three weeks she was on alternate days sleepy and exhilarated. This condition gradually merged into one of mild depression. This did not clear away for eight weeks more. During the depression she was troubled with wakefulness. At no time was she so dull as to take to her bed. She read her Bible considerably, but her depression was not sufficient to be called such by one not knowing her natural condition.

The hospital records contain the history of a male patient, a case of *folie circulaire*, whose periods of excitement were from two to four months, and the depressed periods fully as long. He, for a period of several weeks, would have alternate exhilaration and depression on the same day.

CASE V. Mrs. J. H., born in Boston in 1827, of

Irish parents. Mother died of paralysis; father was intemperate, and subject to fits of melancholy. She was married at the age of fourteen. The early history of the case is very imperfect, nor is there any record of the number or duration of the cycles.

At the age of twenty-eight she had probably the first attack, and was sent to the McLean Asylum. Subsequently, she went to the Taunton, Boston, and Danvers hospitals. For thirty years, at least, she was subject to attacks of depression and exhilaration in alternation. Her friends were in the habit of calling her "well" when exhilarated, although she was far from well at any time. This was because she was more unfitted for the ordinary duties of life when depressed, and it was during her depression that she went to hospitals for care. But at no time was she able to manage her own house. When exhilarated, she had less judgment, and was more troublesome than when depressed, but fears of suicide led to her commitment to a hospital at such times.

When excited, she would always do very foolish things, or make very foolish purchases "to do good." At the time of the Rebellion she appeared in the streets of Boston one day dressed in red, white, and blue, thinking that by this patriotic demonstration she could accomplish some great good. At another time she bought a whole barrel of mouldy crackers, paying the price of good crackers. In extenuation of her folly, she explained that they might be given to somebody's hens. When further pushed, she said she had a good barrel, at any rate.

At another time, seeing a lot of buckets at a low price, she bought the lot, having no use for them.

Her periods of depression were usually preceded, it is said, by some slight depressing incident, and did not appear to come on at a given time, regardless of circumstances. When depressed, she thought herself very poor, and consented to much poorer fare than she would when exhilarated, saying she ought not to eat what others had earned.

In one period of depression she refused to drink, thinking her daughter was trying to poison her. She would worry much about religious affairs, and read much religious literature, and would complain that the more she read, the more condemned she felt. Complained of impulses to injure herself and others, yet at no time did she even attempt suicide, or show any violence. She was inactive and hypochondriacal. Would be watchful and suspicious, thinking people were trying to steal from her. Sleep was poor at these times. These attacks lasted several months.

There were no distinct same periods, as nearly as the writer could learn, but the excitement or exhilaration was not uniform during the time when not depressed.

There was one unusual incident in the course of this patient's career: In 1885, during a period of marked exhilaration, there arose real causes for anxiety. At the same time, the patient suffered from a felon. These exciting causes apparently brought about a condition of delirious, maniacal excitement, for which she was sent to the Danvers Hospital. She soon became rational, but had no memory of the commitment, nor of her sickness at that time.

Later the same year, when depressed, she was committed to the Boston Lunatic Hospital. She was inactive and hypochondriacal, constantly complaining of a weak suicidal impulse. She was found to have dia-

betes mellitus. Two months after admission she died from pulmonary thrombosis, due probably to her inactivity.

CASE VI. Mrs. D., born in 1829. American, school-teacher. One paternal uncle insane. One paternal aunt depressed for a time. One maternal aunt had two or three attacks of depression. One maternal cousin was insane.

For fifteen years she has been subject to attacks of depression, lasting several months, once a year. After she had had several of these she was noticed, when not depressed, to be exhilarated and active and wanted to travel constantly. This exhilaration was not so marked as to cause others to suspect insanity. The periods have grown longer the past seven or eight years, so that for the whole year she has been either depressed or exhilarated, passing gradually from one to the other.

At the age of fifty-seven she went to Florida on business in the spring. She became depressed there, and for six months she left the house only twice. When depressed she was always in the habit of keeping in the house.

She returned to New England in October, still depressed. In a week she became acutely maniacal with delusions of persecution. She requested protection from the police, mayor and detectives. She was sent to the hospital and proved to be most violently excited. Refused food for many months, had hallucinations of hearing, assaulted attendants, destroyed clothing and was extremely noisy. This unusual condition can not be called the excitement of *folie circulaire*, and as the case is under observation still, it is hardly time to report the case.

CASE VII. Mrs E. H., American, born in 1820. Near the age of fifty she had an attack of melancholia lasting four months. At the age of sixty she had a second attack lasting eighteen months. Was very depressed and thought she was going to starve.

Three years later she had a third attack of depression with same delusions as before. Was excited and required restraint for a week. Suffered much from *arthritis deformans* and dyspepsia. This condition lasted for five months when she became cheerful and rational. In February following, four months after becoming cheerful, she was at once very talkative, exhilarated and restless, made a nuisance of herself in the ward, talking constantly. This condition passed away in two months.

She soon went home and continued well for six months. She then returned to the hospital voluntarily, depressed and suffering from dyspepsia. She was soon profoundly depressed, thought she had no oesophagus and refused to eat.

She recovered in the spring again, and remaining rational for three months, she went home but was obliged to return within a week she was so confused and exhilarated.

She then passed into a condition entirely new for her. Was destructive, and noisy at times. Ate very well and digestion gave her no trouble. Was full of delusions and acted very queerly under their influence. Would not answer a question but go through a pantomime. Took one of the doctors for her son. Would tear her hair, run out in the hall in night-dress and was extremely troublesome.

October 21st, 1886. This condition continues unchanged. It is now four months.

## REPORT ON OBSTETRICS.

BY CHARLES M. GREEN, M.D.

## CHLORAL HYDRATE IN OBSTINATE VOMITING OF PREGNANCY.

LEON reports<sup>1</sup> the case of a sexti-gravida, strong and healthy, but the victim of constant and severe vomiting in all her pregnancies, once or twice associated with ptalism. In the sixth pregnancy Leon tried all the usual remedies without success, including ice and iced drinks, iced compresses to the epigastrium, brandy in large and small doses, and dilatation of the os. (The uterus was in normal position and the os not eroded.) The patient ultimately became almost unconscious and could not recognize her friends. Leon then ordered chloral hydrate, in forty-grain doses, to be administered *per rectum* every six hours. Immediate relief followed, and at the end of the first day the patient could sleep quietly. This treatment was kept up for some days, when the patient began to beg for food. She was then allowed to eat what she chose, and there was no return of the nausea and vomiting.

[Simmons, of Yokohama, reported<sup>2</sup> four cases of excessive vomiting in pregnancy, which were immediately relieved by chloral, thirty grains *per rectum* morning and evening. Richardson has also reported<sup>3</sup> three successful cases. Chloral is therefore well worth trial in this occasionally distressing and even fatal complication of pregnancy.—REP.]

## THE UTERINE BRUIT.

ANDREIEW<sup>4</sup> has examined one hundred and fifty-eight cases of women in labor, and in the lying-in period with reference to the uterine bruit. The results of his observations are as follows:

1. While before the birth of the child the uterine bruit shows a varying condition, after labor it is always of the same character, weak and distinctly intermittent.

2. There is no case in which, with careful and repeated auscultation, one can miss hearing the bruit.

3. The most frequent seat of the bruit is about the same before as after labor, and for the most part is found in the left or right side of the uterus, or on both sides at the same time; but it is more frequently heard on the left side than on the right. [Doubtless on account of the customary right lateral torsion of the uterus, which brings the vessels on the left side of that organ into closer proximity to the anterior abdominal wall.—REP.]

4. The strength of the bruit after labor is influenced by the involution of the uterus: the more rapid and complete the involution, the weaker the bruit; but this relationship is not without its limits.

5. The position of the puerperal uterus is without influence on the strength and seat of the bruit: the same is true of the seat of the placenta.

6. The bruit persists after labor for various lengths of time: in healthy puerperae on the average fifty-seven hours; in the sick, ninety-nine hours.

7. The uterine bruit is not a sure sign of pregnancy, as it also occurs in other conditions of the uterus.

8. The bruit is more frequently observed in interstitial than in sub-peritoneal myomata: its presence proves a marked vascular development.

## THE CERVIX AND THE LOWER UTERINE SEGMENT.

Perhaps the most important contributions to obstetric literature during the past year have been the works of Chiari, Waldeyer and Schröder, concerning the relations of the gravid and parturient uterus represented by frozen sections and described in appropriate text.

WALDEYER's work<sup>5</sup> consists in a description of the appearances of frozen sections of a gravida at full term, who was killed by a locomotive. As death had taken place before labor pains had begun, there was naturally no visible "contraction-ring"; but the uterine muscle just above the internal os in front and behind was a little thinner than elsewhere. The normal length of the cervix was preserved and the internal os closed,—another proof that there is no real shortening of the cervix during pregnancy. The internal os lay below the plane of the pelvic brim: the uterus was soft and did not preserve a regular, symmetrical ovoid shape, but adapted itself to its surroundings.

SCHRÖDER,<sup>6</sup> with the coöperation of Stratz, describes a frozen mesial section of a woman dead in the first stage of labor. The anterior wall of the cervix measured 3.7 cm.; the posterior wall was elongated to 5.5 cm.: the os internum was dilated to a diameter of 4.8 cm., and was sharply marked off from the uterus. Above the os internum, both in front and behind, the uterine wall was especially thin, and the contraction-ring was 5.5 cm., above the os internum in front and 3.5 cm. behind. The first effect of labor in this patient, therefore, was to canalize the lower uterine segment and cervical canal. These observations are in accord with Chiari's. According to Schröder and Stratz the uterus at the end of pregnancy is made up of three different parts,—the part capable of retraction, the lower uterine segment, and the cervix. The lower segment undergoes no active contraction during labor. The boundary between the contracting and retracting part above and the progressively thinning and non-contracting segment below is the "contraction-ring"; while the os internum separates the lower segment from the cervix. With the beginning of uterine action, contraction and retraction go on together in what might be called the working portion of the uterus, the contraction-ring rises, the lower segment becomes distended and thinned, and the fetus is driven down into the expanded lower segment and cervix.

The second part of Schröder's work<sup>7</sup> was prepared by HOFMEIER, and is devoted to the consideration of the cervix and lower uterine segment in their anatomical and physiological selections. After a critical examination of the views of other writers on this point, the author describes a number of instructive frozen sections.

In the first place it is clearly established that the cervix to the last moment of pregnancy is preserved as a canal, and is usually filled with cervical mucus. It is possible, however, that during pregnancy the

<sup>7</sup> Centralblatt für Gynäkologie, 1886, No. 30.

cervix may undergo more or less funnel-shaped dilatation, the result of preliminary and oftentimes painless contractions. Regarding the lower uterine segment, Hofmeier is convinced by anatomical facts, macroscopical as well as microscopical, that this portion is not derived from the cervix, as many authors claim, but from the body of the uterus. And he agrees with Schatz that during labor the uterus is divided into a markedly distended portion (thinned even to the point of rupture in certain cases) and an actively contracting part, that is, uterine body. The union of these two portions is strongly marked under the influence of good pains by the contraction-ring, which can be demonstrated by palpation in favorable subjects.

#### PUERPERAL INFECTION BY CONTACT.

As long ago as 1865 Lefort emphasized the significance of contact-infection in contrast with air-infection in a number of infectious diseases, but especially in diseased conditions of wounds and in puerperal fever. In a brief paper<sup>8</sup> he now cites as evidence on this subject an account of an epidemic of puerperal fever which numbered among its victims the daughter of a colleague. For the sake of the greatest possible protection against infection, the patient was delivered at her country-seat; but she died nevertheless of puerperal peritonitis. After careful search for the source of infection, it appeared that the nurse in attendance had recently lost four women in a similar way, while in the practice of both the physicians living in that vicinity and of all the other midwives in the place no case of puerperal fever had occurred. The original infection of the nurse had proceeded from a case of fistulous abscess of the thigh, whence in the opinion of Lefort the pathogenic organisms had been carried.

As there was no law in France whereby the midwife could be prevented against her will from exercising her calling, she infected two more women with fatal result, in spite of warnings by the Prefect. Finally, for a material indemnification for the loss of her time, she consented to spend two months in travel. In England, adds Lefort, she would have spent two years in prison.

[Authenticated cases like the above are valuable in convincing obstetricians of the importance of a rigid system of antisepticism in all cases, and of special disinfection both of doctor and nurse after attendance on septic patients. It should be the duty of the physician to see to it that the nurse he puts in charge of a case has properly disinfected her clothing and her person, and that she never touches the patient's genitals before, during or after labor without having previously made proper use of an antiseptic solution. The statistics of lying-in hospitals show that where antisepticism prevails, puerperal fever is unknown. — REF.]

#### HOW TO DISINFECT THE HANDS.

Since the almost universal acceptance by obstetricians of the views of Semmelweis and Koch concerning the aetiology of puerperal fever, — that this affection always originates from the entrance of septic material through lesions in the genital canal, and since it has at last come to be admitted that the fingers of the nurse and physician are the chief means of introducing micro-organisms to the numerous loci of absorption, it has become a matter of great importance that

it shall be accurately known how the infectious germs inevitably lurking in the innumerable creases and fissures of the hands, in the ungual folds, and under the finger-nails can be effectively sterilized.

At a meeting of the Hamburg Medical Association, Kümmel<sup>9</sup> has given the results of his experiments in this matter, first testing with his hands in what might be called their normal condition, and then with the hands infected by contact with known septic material. His method was to dip his hands, still wet with the disinfectant experimented with, into nutritive gelatine, the subsequent examination of which would disclose the germ-killing efficiency of the various disinfectants used.

To cleanse hands in their normal condition Kümmel found it was sufficient to wash them with hot water, soap, and nail-brush for three minutes, and then for one minute with 0.6 per cent. thymol solution, or 0.1 per cent. sublimate solution, or 3 per cent. solution of carbolic acid. But to thoroughly cleanse infected hands there must be a good scrubbing with hot water, (preferably) potash soap, and brush for five minutes, followed by brushing for two minutes with 5 per cent. carbolic solution or chlorine water. Of course the exposed part of the arm should be included in the process.

[The importance of Kümmel's paper lies largely in his explicit direction about soap and water cleansing before the use of the selected disinfectant. Probably no antiseptic, however potent, is efficient when the hands are simply dabbled in it. A nail-brush should therefore be included in the obstetric bag; and the common soft soap to be found in most kitchens, or the yellow laundry soap, should be faithfully used with brush and hot water, as a necessary preliminary to efficient disinfection. — REF.]

#### THE VALUE OF ANTIPIRYNE IN PUERPERAL FEVER.

In a discussion on the treatment of puerperal fever at the first meeting of the German Gynecological Society in Munich last June, it appeared that by many prominent obstetricians the use of antipyrine in that disease had been abandoned. Mundé, who was present at the meeting, was led on his return to New York to give<sup>10</sup> his experience with the drug, which has seemed to him of great value in suitable cases. While admitting that the effect of antipyrine is but temporary, Mundé believes that, in the intervals of comfort and comparative apyrexia which follow the use of the remedy, the patient is enabled to recuperate by sleep and to accumulate vital force which has been consumed by the fever: time is thus gained in which the patient may throw off the poison, and in which the other remedies so important in this disease, — the cold coil, stimulants, and nutrients, and above all appropriate local treatment, can be used. Mundé has advised using the drug during the past two years in nineteen cases of puerperal septicæmia and in nine cases of puerperal peritonitis seen in consultation, and of these twenty-eight cases only three proved fatal.

Mundé disbelieves in the use of large doses; twenty to thirty grains repeated every hour or two until sixty or ninety grains have been given, he considers exceedingly hazardous, on account of the likelihood of serious collapse. He begins with a dose of twenty grains, if the patient is strong, and follows with five or ten grain

<sup>8</sup> Gazette des Hôpitaux, 1886, No. 1; Centralblatt für Gynäkologie, 1886, No. 46.

<sup>9</sup> Deutsche Med. Wochenschrift, 1886, No. 32; London Medical Record, November 15, 1886.

<sup>10</sup> New York Medical Journal, October 9, 1886.

doses every half-hour or hour, until twenty grains more shall have been taken. If the patient is weak, he begins with but ten grains, and then gives five grains every half-hour, until twenty grains more shall have been taken, making thirty grains in all. At the same time the pulse is carefully watched and any sign of flagging is a signal to discontinue the drug and give stimulants. When the temperature rises above 102°, the drug is repeated in the same manner, in the above-mentioned, or even smaller, doses; but Mundé has seldom found it necessary to order the thirty or forty grains in divided doses to be given more than twice in twenty-four hours, generally only once and that usually towards evening. As soon as the temperature falls below 101°, the drug is discontinued. The author believes the remedy is best given in solution with syrup and water, five grains to the tablespoonful, or in gelatine capsules, or again in suppositories or by enemata: it may also be used hypodermically, as the drug is readily soluble, one grain to a minim of water. From his somewhat extended use of the drug, Mundé can report most satisfactory results.

[Perhaps one of the most forcible arguments against the use of antipyrine is the fact that with the fall of temperature many practitioners would be led by a false sense of security to omit the local and systemic measures so essential to the successful treatment of puerperal septicæmia. This is, of course, no argument against the intelligent use of the remedy recommended by Mundé, who employs the drug only as an adjuvant to appropriate local and general measures. It should not be forgotten, however, that antipyrine is a drug powerful for good and evil; and that except to the practised observer it may temporarily so mask the symptoms of septicæmia that the medical attendant may relax his attention to local conditions, in the belief that a fall of temperature, thus artificially produced, indicates abatement of the disease itself.—*Rev.*]

### Clinical Memorandum.

#### A CASE OF CEREBRAL DISEASE, COMPLICATED WITH PREGNANCY.

By R. L. HODGSON, M.D., OF ARLINGTON.

Mrs. D., aged thirty-three, mother of four children, one of them idiotic of very low type. During her pregnancies she had no excessive vomiting. She had good health uniformly, except an uncomfortable feeling in back of head at times, for which she had consulted a physician when in New York in May, 1885. He did not attach much importance to the feeling, and so told her. Her father died in the McLean Asylum of some affection of the brain.

I was called to prescribe for her on October 29th, 1885, for troublesome vomiting. She had menstruated last about the middle of September. The vomiting began about a week before my first visit, more than a month after the last menstruation. She supposed herself pregnant, and I, thinking her case one of the common vomiting of pregnancy, made a simple prescription, and did not see her again for some days. On my second visit, I learned that the day before the vomiting began, while she was in a carriage, the driver whipped the horse so that he started with a jerk, and she felt something give way in her back. On vaginal

examination, the uterus was found prolapsed and retroverted. It was readily restored to its normal position and easily kept there by a pessary. She was in bed, and not disposed to get up. There was no relief to the vomiting after the replacing of the uterus. Vomiting persisted and increased, so that within a week nothing was retained by the stomach, and recourse was had to nutritive enemata.

At this time, and during the whole course of the disease, there was marked hyperæsthesia of the skin, the slightest touch causing her to shrink, and sometimes to cry out. She was very averse to making any exertion. When asked to place herself in position for examination, she would say, "Wait a little"; when asked again, she said, "Don't be impatient with me." Only after repeated urging would she place herself in the required position. Though these symptoms, with the vomiting, raised the question of disease of the brain, yet as there seemed no hysterical element in them—for instance, deep pressure being borne better than light—all the symptoms were interpreted as the results of the pregnant condition. The next three weeks showed little change.

Enemata of soups, broths, emulsion of sweetbreads and milk were the sole nourishment, except Murdoch's Food, which the nurse added to each enema. All the enemata did well except milk, but whenever milk was given she complained of a fulness and pressure in the head, which was not relieved till after a dejection. The last week in November she began to retain some food. The enemata were given at longer intervals, and she was nourished largely by food by the mouth. The uterus was at this time increasing in size, and kept in place without artificial support. She gained strength and began to take some beefsteak and to sit up a short time. December 7th, she sat up, received a caller, and wrote a card to her mother, saying she was getting well. That night the sick child, as the idiotic one was called, made a great noise in another room, and excited the mother. The next day the vomiting was greater, and there was excitement and an inclination to talk whenever any one was with her. There was from the first a desire to talk more than was her custom, and about private affairs. The next four weeks the vomiting varied in degree, but was so much that she was nourished largely *per rectum*.

She had during that time periods of excitement in which she talked a great deal, but always rationally and coherently, though there was loss of memory and confusion about time. The periods of excitement were usually followed by sleep, which she said refreshed her, and she would say, on awaking, "I feel I am getting better." Up to January 6th, 1886, there had been no delirium, no convulsion, no paralysis, though there had been morbid sensibility, disturbance of volition, and of memory. The pulse had been normal, temperature not observed, though nothing indicated a change from normal. Defæcation and micturition had been regular and natural. On January 13th, after a long period of excitement, in which she talked with difficulty, having apparent aphasia, there was a long sleep. On the morning of 14th, there was a convulsive movement of the left arm, lasting some minutes. Then came on active delirium, with very frequent pulse and hot, dry skin. This state of things lasted through the 14th and 15th, and up to three o'clock on the morning of the 16th, at which time she sunk and died, the delirium being very active to the last.

**Treatment.** The early symptoms in this case would have aroused grave suspicion of disease of the brain had not pregnancy come in as a probable explanation of them. I was sustained by two gentlemen who saw the patient in consultation, in my opinion that, though the brain was suspected, the symptoms were probably reflex. Later developments made it clear that there was some lesion of the brain, and the autopsy, that great aid in diagnosis, made by Dr. Fitz, settled all doubts. The body was found fairly well nourished. The uterus was found *in situ* well developed and containing a well-developed fetus of about four months. No organ showed anything abnormal till the brain was exposed. There the arachnoid was darkened, injected and thickened. In each hemisphere of the brain, close to the longitudinal fissure, were two or three hemispherical depressions large enough to admit the end of a common-sized finger. One of the depressions was filled by a cyst containing a limpid serous fluid. Dr. Fitz gave as the cause of death chronic arachnitis, with atrophy of the brain.

### Reports of Societies.

#### PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. M. GREEN, M.D., SECRETARY.

DECEMBER 11, 1886, the President, DR. A. D. SINCLAIR, in the chair.

DR. R. L. HODGDON reported a

#### CASE OF CEREBRAL DISEASE COMPLICATED WITH PREGNANCY.<sup>1</sup>

DR. C. E. STEDMAN alluded to the case of a young woman, who in labor at term was seized with convulsions of peculiar character and died soon after delivery: there was paralysis of the right arm. The cause of death was found to be cerebral hemorrhage.

DR. SINCLAIR had seen in consultation a case in the ninth month of pregnancy complicated with some disease of the brain. The patient was comatose and moribund: the child was alive, however, and he advised immediate artificial delivery; but neither the attending physician nor the husband would assent to this, and both lives were lost. The nature of the disease was not apparent and autopsy was refused.

DR. ELLIOT reported ~

#### A CASE OF CHRONIC SALPINGITIS WITH SUPPURATING TUBO-OVARIAN CYST: OPERATION, RECOVERY.

DR. BLAKE said that before the days of laparotomy the treatment of cases like this was by incision and drainage *per vaginam*, followed by months of suffering before recovery, if indeed recovery occur.

DR. BAKER believed that not infrequently cases of supposed pelvic abscess would prove to be like the one reported, if laparotomy were done to make a clear diagnosis: early laparotomy for diagnostic purposes he believed to be a justifiable and valuable procedure in all doubtful cases. He thought the fact that some medical men see so many cases of salpingitis, while others see comparatively few, was susceptible of an easy explanation: in large public hospitals, like Bellevue, for instance, are to be found many gonorrheal

patients, and the staff of such a hospital would naturally see a larger proportional number of cases of diseased tubes, which are chiefly of gonorrheal origin, than the staff of a hospital like the New York Woman's Hospital, which has a different clientele and not so much gonorrhea.

DR. DRAPER had observed in the *post-mortem* examination of acute cases of criminal abortion, in which inflammatory changes had proceeded from the endometrium to the tubes and thence to the peritonæum, that the dilatation of the tubes increased uniformly from the uterine opening outward, so that the tubes presented a funnel-shaped appearance. He asked DR. ELLIOT if such was the character of the dilatation in his case.

DR. ELLIOT replied that in the case reported the end of the tube connected with, and opening into, the cyst was about one-eighth of an inch in diameter: the tube itself was sacculated, the pouches being big enough to admit the thumb; between the sac-like dilatations the tube was constricted. The tube-walls were much thinned in the dilated parts.

DR. STRONG said that cases like Dr. Elliot's, in which the diagnosis was made before operation, and in which the result was so excellent, would go far towards stemming the current of abuse against the operation; and they should also win favorable opinions of diagnostic laparotomy in doubtful cases. He had observed one case of salpingitis known to be the result of gonorrhea contracted from the husband. At first the inflammatory process was limited to the vagina and the patient was treated with vaginal injections; but later there ensued pain in the right side, and flowing, and he found the right tube distended to the size of a sausage and excessively painful. The patient recovered and is now well. He had also seen a case which much resembled Dr. Elliot's, the patient having a profuse, mal-odorous discharge, the disease being of four years standing: she has disappeared from his observation and he did not know the final issue of the case.

DR. ABBOT inquired if salpingitis was often the immediate result of acute gonorrhea, and directly traceable to that affection.

DR. ELLIOT said that salpingitis was a late manifestation of gonorrheal infection. Among all cases of gonorrhea, salpingitis occurs infrequently; but, as the number of gonorrheal patients is large, the absolute number of cases of salpingitis is also large. In small communities the disease would be rare: he believed, however, that it was more common than generally supposed, and thought that cases of so-called uterine colic are probably oftentimes affections of the tubes.

#### LIGATURE OF THE FUNIS.

DR. HODGDON spoke of an accident, quite unique in his experience, that had recently occurred to him. In tying the funis with a piece of twine he had completely cut it through, and the blood spurted freely. In answer to a question he said he had frequently cut the funis, without tying it, after pulsation had ceased, and had never known the funis to bleed; but he never dared to leave the house without having applied a ligature.

DR. RICHARDSON reminded the society that several years ago he had reported to them the results obtained by him in fifty consecutive cases in the Boston Lying-

<sup>1</sup> See page 59 of this number of the Journal.

in Hospital, in which the cord was cut without tying. After the cord had ceased pulsating it was cut with dull scissors and the child watched: in no instance was there any hæmorrhage; in fact, hæmorrhage could not be induced by stripping the cord or other manipulations. He asked if any member had been troubled with secondary hæmorrhage from the much-twisted, oedematous funis: this accident had occurred several times in his experience.

DR. DAVENPORT had seen one case in which an almost fatal umbilical hæmorrhage occurred four hours after birth.

DR. FORSTER had lost one infant from this cause. He believed the best ligature for the funis was that used in Dublin,—three strings knotted together at the ends, making a cord with three strands; such a cord is strong and will not cut.

DR. COTTING said there was nothing better than a number of strands of thread knotted together at the ends: thread could be found in the poorest house.

DRS. INGALLS and DOE had found narrow linen braid strong and serviceable.

#### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M.D., SECRETARY.

DECEMBER 27, 1886, the President, DR. F. W. DRAPER, in the chair.

DR. O. F. WADSWORTH read a paper on the

#### AMBLIOPIA OF SQUINT.<sup>1</sup>

DR. HAY said that after the very able presentation by Dr. Wadsworth of one of the difficult subjects of ophthalmology, he could hardly hope to interest the Society. He would, however, say that for some years he had been accustomed to act in accordance with the views advocated in the interesting paper to which he had just listened. There are two aspects of the subject which especially present themselves to our attention. The theoretical question: Is the inferiority in vision of the squinting eye, which frequently occurs, a consequence of the squint? would it have been prevented if we could have corrected the squint sufficiently early? Then the practical question: Should the operation be done early, as a rule?

The first question can hardly be determined with certainty, for we cannot measure the vision of an infant. The opinion that the defect is a consequence of the strabismus is based on theories, which, however, are not accepted by all authors. The view is that, in consequence of so-called corresponding retinal points, which are anatomically pre-determined, the deviation of one eye would cause double vision, and that to remedy this, there is an instinctive suppression or ignoring of one of the images—that of the deviating eye; and further, that this suppression reacts injuriously on the function of the corresponding visual apparatus.

But, on the other hand, some authors doubt the existence of such anatomically-determined points; and so, in the infant, at the commencement of life the diplopia would not be a necessary consequence of the deviation, as at first, without corresponding retinal points, there would not be binocular single vision; and without this, no proper diplopia. Later, after corre-

sponding points had been acquired; if strabismus should occur, at first there would be diplopia, but binocular fixation might be unlearned, and new arrangements made adapted for the squint, each eye seeing for itself.

As to the practical question, that of early operation: Even supposing the frequent ignoring, on the part of the mind, of the impressions transmitted to the brain from one retina were followed by some reaction injurious to the function of the corresponding retina, conducting fibres, and visual centre, or of parts of them; yet it would only follow that in cases in other respects suitable, we should operate as soon as convenient, for some cases of strabismus are not best treated by cutting. There may be spasmodic cases of reflex origin, or paralytic cases with disease of the brain; also cases with disease of the squinting eye, such that we should not expect any improvement of vision of the eye to result from the tenotomy. As to the numerous cases with a high degree of ametropia, it seems preferable, on some accounts, to postpone the operation till after the age when the child could wear glasses to advantage, in order that the effect of these might first be tried.

As matter of fact, early operation is not always successful in correcting the deformity or in preventing subsequent inferiority of vision in the squinting eye; and indeed, in general, the effect of ocular tenotomy disappoints the operator. If the strabismus were of high degree, and seemed of a kind likely to be relieved by cutting, he should prefer to operate early; but if slight, and especially if there were doubts about its pathology, the operation might be postponed, although, regarding the vision of the infant as something imperfect and in process of development, it seems desirable to remove as soon as practicable any abnormal conditions which might interfere with this process. In a high degree of strabismus, the movements of the eyes are restricted, and adults sometimes experience a sense of relief after the operation.

DR. CHARLES H. WILLIAMS called attention to the poor vision which was often found in convergent strabismus, even in the better eye, the records at the Infirmary for the past year showing the vision to be normal in only sixteen out of some forty cases.

CASES OF CONVERGENT STRABISMUS, WITH HYPERMETROPIA.

	1	0.9	0.8	0.7	0.6	0.5	0.4	0.3	0.2	0.1	<0.1
Vision Equals,	5	-	-	2	1	1	1	4	7	12	9
Squinting Eyes,	16	3	1	8	1	2	5	3	2	1	-
Other Eye,											

The number of cases in which hypermetropia was present with convergent strabismus, suggested that a certain amount of the amblyopia might be an acquired form, for as the squint is generally developed in early childhood, when the eyes are first used to any extent for near objects, the child may unconsciously find that, by squinting, he can continue the accommodative effort more easily; and in order to avoid diplopia, he suppresses the recognition of the visual impression from the squinting eye at the visual centre, as when one uses the microscope.

If the strabismus is constant in one eye, we may find, by the time the child is old enough to be tested with any accuracy, that a considerable amblyopia already exists from suppression of the images, which would not afterward be changed, and which, so far as our means of testing go, would appear to be congenital.

<sup>1</sup> See page 49.

Dr. WADSWORTH said, in closing the discussion, that the question of retinal identity seems to be introduced by writers rather to explain loss of double vision that was noted. It does not seem especially pertinent to explain the existence of amblyopia, congenital or acquired. He supposes that double vision may occasionally exist in the young child without being complained of, and occasionally we do hear complaints in such children. Dr. Williams may, without doubt, find in the public charities a large proportion of cases with disordered vision. Such abound in all public clinics; their consideration was thrown out from his paper as only complicating discussion. No doubt, hypermetropia is the more common error of refraction in convergent, as myopia is in divergent strabismus, but this does not seem to have any bearing on the immediate question.

#### BOSTON MEDICO-PSYCHOLOGICAL SOCIETY.

PHILIP COOMBS KNAFF, M.D., SECRETARY.

MARCH 18, 1886. Dr. DENNY presiding.

Dr. WALTER CHANNING read a paper,

#### REPORT OF A CASE OF EPILEPSY OF FORTY-FIVE YEARS' DURATION, WITH AUTOPSY.<sup>1</sup>

Dr. FISHER said that the case seemed very unusual, and was of interest as being a traumatic case where an operation did no good. A case was recently reported where trephining cured the convulsions in an old case of epilepsy with dementia, although, of course, the dementia itself was not cured. The case, however, was reported too soon after the operation to say with certainty whether there was a complete cure of the convulsions, for many epileptics improve temporarily on new treatment. He spoke of several cases of insanity with a probable epileptic basis. The first case was a boy of seventeen who had had epilepsy since the age of five. After a series of convulsions he was brought to the Boston Lunatic Hospital in a condition of the most extreme suicidal melancholia. He had few convulsions in the hospital but he had to be watched constantly. He finally became exhausted and died of pulmonary embolism. The gross appearances in the brain were healthy. The second case was a young man who had had two or three attacks of doubtful *petit mal*. After a period of some mental anxiety he was found in his room, in a position of opisthotonus, groaning and biting his finger. After he had had one or two attacks he was taken to the hospital, where he made a perfect recovery. In the attacks he became rigid, and then extremely maniacal. The third case was a lady, with a history of apoplexy in the family. For twenty years she had had attacks of unconsciousness without convulsions. For some years she had been a nervous invalid and now she had very vivid hallucinations of sight and hearing which were unilateral.

Dr. J. B. AYER spoke of a case of recovery under treatment. The patient had had attacks for seven years which were increasing in severity. They began with a cold aura in the epigastrium, and the patient believed that he had stopped some by pressure on the hypochondrium. He took the bromides for three years, and has now been free from any trouble for three years.

Dr. COWLES said that the confirmed epileptics seen in asylums were more curious than interesting. As a rule, the cases hardly repaid study and the autopsies often showed nothing significant. In the case reported the epilepsy was certainly secondary to the trauma, coming on some years after and showing a progressive character. The patient must have had great psychical stability to have withstood all this for so long. It was often hard to decide, in an asylum, whether convulsions were due to hysteria or epilepsy. He quoted a case where anomalous attacks of *petit mal*, with slight unconsciousness, developed after a fright; hystero-epilepsy appeared later. Another case, a girl of twenty, used to have attacks during which her face would flush and she would sit back and close her eyes, although she retained consciousness. After one of these attacks she went into an epileptic state, a condition of mania and hysterical excitement. One of these attacks lasted a fortnight and she had no consciousness of it. In the interval there were no signs of hysteria, but bromide made her worse.

Dr. BOLAND asked if it were proper to call convulsive attacks due to some gross lesion epilepsy. The case reported did not seem to show the mental deterioration of ordinary epilepsy.

Dr. KNAFF said that the question was whether epilepsy should be the name of a distinct disease or merely of a symptom-complex. There is a distinct disease due, as Hughlings-Jackson thinks, to the occasional discharge from certain cells in the cortex whose molecules are in a state of unstable equilibrium. In these cases, after death, we can discover no lesion. This disease must certainly be distinct from similar motor or psychical discharges due to some gross lesion, such as tumor or meningitis, or some poison, such as is present in uræmia. Clinically, however, these cases are often indistinguishable from true epilepsy. Personally he preferred to limit the term "epilepsy" to the first-named condition, and speak of "epileptiform attacks" in cases where a gross lesion could be demonstrated.

Dr. CHANNING said that there were many varieties of epilepsy. Jackson's theory of discharges was a theory of a pathological process based on something, but what was the something? Epilepsy was often traumatic, an effect following a cause, the discharge being simply what took place. Epilepsy, like hemiplegia, was a symptom-complex. Such external manifestations might well be called epilepsy, except where special symptoms warranted us in calling them epileptiform, epileptoid, or hysterical. There seemed no reason for modifying the name. Larvated epilepsy, as seen in criminals, was of great interest. Under other surroundings the case reported might have ended in homicidal or suicidal frenzy. He had seen several such cases with attacks of violence.

Dr. DENNY said that the portions of the cranium and brain exhibited illustrate how epilepsy and insanity sometimes supervene upon a blow without external evidence of a traumatic injury to the skull. The question is suggested, therefore, what is the evidence which, in the absence of any other sufficient cause, shows that these attacks were of traumatic origin. In the first place it is significant of a relation of cause and effect that the most marked pathological changes occupy the line drawn from the point of impact on the frontal bone, and continuing posteriorly along the whole central line of the falx cerebri. Thus the ethmoid is involved in a chronic inflammatory pro-

<sup>1</sup> See this Journal, Vol. cxv, p. 4.

cess, which accounts for the degeneration of the olfactory nerve and its loss of function. Again the falx cerebri attached to the crista galli of the ethmoid is markedly thickened by a chronic pachymeningitis. Furthermore the anterior communicating artery is reduced to an impervious cord by endarteritis, and from this point onwards the cerebral arteries are much diminished in calibre by inflammatory deposits, thus interfering seriously with the circulation and nutrition of the brain, which results in morbid irritability of that organ from anemic conditions, such as are characteristic of epilepsy in general. Again, one of the results of traumatic injury of the brain is an exaggerated chronic mental excitability, which is sometimes the foundation of subsequent epileptic insanity. While progressive dementia with paralysis follows injury to the skull in some cases, yet in another class of cases an injury is followed by a frequently recurring state of excitability with cerebral congestions and epileptic insanity, which is not characterized by the local spasms, such as result from circumscribed injury of the cortex cerebri. The alternating form of symptoms seen in the case described, as shown by the regular recurrence of days of excitement and depression, may be referred to the tendency to periodicity of changes in the cerebral circulation observed in epilepsy, as well as in the related forms of periodicity observed in *folie circulaire*. The combination of the two in this case gives it peculiar interest as illustrating this relation.

October 21, 1886. DR. GORTON in the chair.

DR. E. B. LANE read a paper

SOME CASES OF ALTERNATING INSANITY, WITH ONE CASE OF RECOVERY.<sup>2</sup>

DR. FISHER spoke of three other cases that had been in the Lunatic Hospital. One was a lawyer who at the age of fifty-five became subject to periods of depression and excitement, alternating for ten years. When depressed he was easily managed, when excited he was active and would not attend to business, although he was manageable. In one period of depression he went to the McLean Asylum, but escaped later. After this he became excited, drank, lived loosely, was talkative and quarrelsome, and was sent to the hospital. He was then exhilarated, witty, extravagant, boastful, and grandiose. Suddenly he became moderately depressed, kept his room, had indignation, aged rapidly, and finally died of exhaustion. The second case was a business man, who had alternating periods for thirty years. When excited he was mischievous, violent, and obscene. On two separate occasions he broke his humerus. The third case was an old lady, now ninety-one, who had been insane for thirty years, with long periods. There is a sudden change from excitement to depression, the depression being stuporous. She was generally lively, and slightly exhilarated; she was complimentary, everything pleased her, and she was supremely contented. As a rule cases of *folie circulaire* do not become demented, but the case first mentioned did. The origin of these cases is curious; there may be a recurrent mania, and the mania may cause depression, and then why may we not have periods of recovery. He spoke of a man who had had attacks of depression for three successive years. It was a question whether there was a slight excess of his natural exuberance after these attacks, but there was no mania, and now he had

had no depression for five or six years. In answer to a question by Dr. Channing, the speaker said that the third case he mentioned had never been known to have any period of actual sanity, but when she was not depressed she was sensible and rational, except that she was unusually happy. In answer to Dr. Page he said that it was hard to judge of the temperament of his cases, as they occurred in old people. One of his cases and one of Dr. Lane's were sanguine and volatile, but it was doubtful whether the sanguine temperament was more prone to the trouble.

DR. PAGE said that we often see sane people who at times are moody and unsocial, and at other times are slightly exhilarated. They have ups and downs, as in mental disease, without any known regularity. In answer to Dr. Channing he said that the patients at the Nervine Asylum varied somewhat in their mental condition, but, as a rule, they were rather a hopeless class.

DR. COWLES said that Clouston states that heredity is the rule in typical cases of *folie circulaire*. The majority of the chronic insane at the McLean Asylum have periods of alternation in their insanity, and go on to dementia, but it is a curious fact that typical cases of *folie circulaire* do not become demented. With one exception Dr. Lane's cases presented no regular cycles. A patient at Somerville, who was insane for three years, for some time had a period of exhilaration and a period of depression, with a slight interval of sanity, each period lasting three weeks. The limitation was very precise, a thing which Clouston says is rare.

DR. H. R. STEDMAN said that the absence of dementia in *folie circulaire* impresses every one. The two states, melancholia and mania seem to counterbalance each other, in their effect on the nervous shock, so, as Falret thinks, there is no resultant dementia. In regard to Dr. Lane's first case he considered that, in his experience, alternating states are quite common in the insanity of adolescence. The rationale is bad heredity, causing instability. In the young there is an additional element, that the mind is not stable or fixed, and is prone to change. In the case in question it would be hard to say whether it was *folie circulaire*, as it had not been long enough under observation. It could hardly be *folie circulaire* if the patient stayed well, for patients with that disease do not get well. If the next attack is like this it will establish the diagnosis. It is more likely to go on to dementia with occasional outbursts, than to develop into a true *folie circulaire*. A knowledge of this tendency to alternation in adolescent patients is valuable in prognosis and treatment. Unfortunately we know too little of the early symptoms of *folie circulaire*; hysteria is a common beginning. In answer to Dr. Lane he said that the cases in youth that he had seen, go on for a time, but the attacks are not regular.

DR. KNAFF said that Dauty had recently reported a case of *folie circulaire* where there were four stages, excitement, depression, dementia, and sanity. The dementia was of brief duration, but it was nevertheless distinct.

DR. TURNBULL spoke of a case where just before the maniacal period there were alternating days of exhilaration and depression, and later the mania reached its height. Here malaria was thought to be the cause. In some cases of melancholia we see a period of exhilaration and reaction after the depression

<sup>2</sup> See this Journal, p. 52.

but they are not *folie circulaire*. In sane people he had noticed periods of depression and exhilaration; the former were merely fits of the blues, the latter were less marked.

DR. CHANNING asked which was the primary form in Dr. Lane's cases, depression or exhilaration?

DR. LANE said that they were about evenly divided. One case began with excitement, but a small majority were depressed.

DR. CHANNING said that the pathological explanation of *folie circulaire* had to be changed in accordance with the primary form of the insanity. If the depression be secondary, it may be considered the exhaustion following the excitement, but not if it be primary. In his own experience the depression had been the primary state. In cases of mania a stage of primary depression is common, but it is usually not noticed. He then mentioned the case of a young man of twenty-five, with alternating insanity. At the age of sixteen he became depressed and had to give up study and go to bed for a few days, after which he was slightly exhilarated. He went to school and college for two years, then broke down and had alternating depression and excitement. In the excited stage he went off on sprees, leaving college for that purpose, and acted very strangely. This alternation lasted six months; he was depressed for two weeks, excited one week, and sane two weeks. For a year after that he was better, and then his attacks returned. For ten days he was depressed, stayed in bed, leading an absolutely automatic life, not answering questions, and taking no care of himself. Then he went on an outrageous spree; he had no delusions, but was exhilarated, uncontrollable, and had much sexual excitement. In the excited stage he had no moral sense or sense of honor, but in the sane stage he was fairly trustworthy. It was, however, a case of primary insanity, with congenital mental impairment, manifesting itself at all times.

DR. GOLDSMITH said that the question of alternation was very interesting and obscure. The cause of *folie circulaire* lay as a rule in bad heredity. It was a constitutional neurosis like *primäre Verrücktheit*. In his own experience it was much commoner in people of fair social position and intelligence. There were six cases of it among one hundred and seventy-five patients at the Butler Hospital, more than among eight hundred at Danvers; at Morningside, too, there were more among the hundred private patients than among the seven hundred paupers. Its onset was almost always by melancholia. Depression after mania is common and has no bad significance, but exhilaration after prolonged melancholia means, as a rule, either *folie circulaire* or general paralysis. Dr. Stedman's cases of alternating insanity in the young are of interest: these are also due to bad heredity, but they never turn out to be genuine *folie circulaire*. The successive attacks in *folie circulaire* do not cause dementia, but in the young dementia soon becomes apparent, and finally the alternations grow less and disappear. The alternation is important in diagnosis and prognosis, especially in distinguishing from moral obliquity. In the healthy mind a normal state, and not an exhilarated state, follows a period of depression. He had known of no case of *folie circulaire* that did well, but one, that used to have cycles annually, had had none for three years.

DR. JELLY spoke of a man, with a bad heredity on

both sides and a syphilitic history, who was, when in college, queer, erratic, a practical joker, and no student. Ten years ago he came to Boston, "ten times himself." He went to one or two asylums, and was very excited and troublesome. After eighteen months he became mildly depressed. This depression lasted eighteen months, and then he was well (?) for two years, held a responsible position, and did fairly well. Then he came back to Boston worse than ever, went to the Superintendents' meeting at Newport and made himself conspicuous. For two years he was greatly excited and very troublesome. Then he became intensely depressed, which condition continues. He realizes his condition, takes no care of himself, and is utterly wretched. Every period so far has been worse than the preceding. The excitement now lasts eighteen months, the depression two years, and the interval a year.

DR. COWLES said that Clouston also states that *folie circulaire* is more common among the educated. It is one way that nature limits overbreeding. There are more cases at Somerville than at any State hospital. Alternations of feeling are common in people with a bad heredity who are not insane. If this be so, as neurotic people are unstable, the alternations come more easily from less profound causes, and the patient gets better and then has other attacks. Simple habit has a great influence. Thus, if there is a facile tendency to alternation, and an impressionability to the causes thereof, we may, with the law of reaction, have a basis for a theory of *folie circulaire* in the readiness of the mind to establish a habit of variability.

DR. LANE said that all but two of his cases were of the better class.

DR. TURNBULL said that Spitzka states that in one case the intervals followed the seasons of the year. He knew of a person, not insane, who had periodical attacks of depression in the spring.

### Recent Literature.

*Handbook of Diseases of the Ear.* By URBAN PRITCHARD, M.D., with illustrations. P. Blakiston, Son & Co.: Phila. pp. 207.

This is a concise, well-written handbook, really adapted to its object, as stated in the preface, of furnishing a practical manual for students and practitioners. It is particularly useful for comparison with other works, as it is confined largely to the author's own experience, and in the matter of treatment especially, there is much of interest, as in some degree different from what is advised in the more common text-books.

The criticism to be applied to the book is the one to which all manuals which deal with an extensive subject are open, a sacrifice of very important details in pathology and treatment to conciseness.

*Handbook of the Diseases of the Nervous System.* By JAMES ROSS, M.D., LL.D. 8vo, pp. xx, 723. Philadelphia: Lea Brothers & Co. 1885.

This handbook, the author tells us, is intended for the student and the "busy practitioner," for whom his former treatise was too bulky. Like the former work, the first part of this is devoted to the anatomy, physiology, and general pathology of the nervous system, and to the general symptomatology and treatment of

its diseases. Dr. Ross showed in his former work his wide reading and his skill in compilation, and the present work is a further indication of his powers. This part contains little that is new or original, but it is in the main accurate, and is as useful a summary as can be found in any one book. Numerous illustrations and diagrams render the subject-matter clearer, although we miss the figures of the motor points, which ought to have been inserted for the "man of one book." In his second part the author has employed a different plan from that followed in his Treatise. He has "adopted, as far as possible, a clinical classification, so that the diseases which are most apt to be mistaken for each other will be found in close proximity. . . . His rule has been to leave out the details of morbid anatomy and physiology." The result is not a success. A work in English on the diagnosis of nervous diseases is desirable, but Dr. Ross has not given it to us, neither has he given us a useful text-book.

In the first place, he abandons his classification at the start for a pathological classification, and, when he returns to it, he arranges his diseases in so comprehensive a way as to include catalepsy, Thomsen's disease, epilepsy, and convulsive tic under the same head. Then he reverts to the ordinary pathological classification again, which continues, with occasional breaks, to the end of the book, when he gives a chapter on general diagnosis, into which is thrust a description of cerebral syphilis. In the individual chapters, we find, first the symptoms of all the diseases together, then their pathology, and lastly their treatment, so that the account of the individual disease must be looked for in at least three places. Neurasthenia, however, has a section to itself, but hysteria is scattered all over the book, and tabes dorsalis does not fare much better. Moreover, although a clinical classification has been his aim, the subject of differential diagnosis has been greatly neglected; thus, chronic anterior poliomyelitis stands out as a distinct affection, and scarcely a mention is made of its similarity to multiple neuritis, while the question whether it has a separate existence is untouched. Myelitis, on the other hand, is divided into nine or ten different forms, whose clinical individuality is, to say the least, doubtful, although an anatomical distinction may exist.

We regret to add that, in addition to the radical defect in plan, many minor errors in the statement of fact have crept into the book, which cannot be noticed here. We must state, however, that the writer has gone back twenty years in considering fracture and hemorrhage as concomitants of concussion of the spine. Some day we shall hear that a broken bone is occasionally found in cases of ecchymosis! Like too many neurologists, Dr. Ross seems to think that there is a great gulf between nervous and mental diseases, so that he scarcely makes mention of general paralysis, and falls into numerous errors in his statements in regard to mental symptoms in general.

On the whole, although the book has much of good in it, it is not useful as a clinical guide to diagnosis, and its faults of arrangement are so great as to render it extremely inconvenient for the class for whom it was intended. The author's style, moreover, is obscure, his grammar is sadly defective, and the book contains too many unusual expressions, such as "le haut mal" in epilepsy, "spasmodic paralysis," and "sclerosis in patches."

### THE PHYSIOLOGY OF THE HAREM.

ORIENTAL woman has for many generations occupied a position in which the one element of sexuality has absorbed into itself all other qualities and functions of her existence. Sex, *et præterea nihil* has represented her value and significance in the national economy, and that not for the primary end of reproduction but of sensuous gratification. The effects of this condition upon her physical and moral nature have been sufficiently illustrated to the western reader by the concurrent testimony of travellers and by the coloring imparted to the poems of Moore and Byron. The physiological results of this mode of life have not, however, beyond the general and obvious statement that the women matured very young, been given us in satisfactory detail.

Much has been said of late of the prejudicial effect upon the maternal function produced by extraordinary intellectual activity in women, and it has seemed that the higher education, with late marriages and much study, was not a favorable preparation for fruitful motherhood. But it is not without interest to know that the women of Turkey, educated almost from birth with a sole view to the stimulation of the generative functions, are quite as infertile as the blue-stockings of New England. Dr. Zambaco, of Constantinople, presented a communication to the Gynecological Section of the last International Medical Congress at Copenhagen, on the general subject of the physiology of oriental women, which has appeared in the report of the Congress and will well repay perusal, not only from its intrinsic interest but because of the light which it throws on the effects liable to follow sexual precocity in any country.

Circumcision is practised, according to Dr. Zambaco, almost universally upon Mussulman girls in all classes of society in Egypt and Arabia. In Egypt, the operation is performed at about the age of seven as with boys. Great ceremonies attend the event. The girls walk in files or ride in carriages to the scene of the operation, decked in all the finery their parents

can give or borrow. The operation is performed by a woman, who makes it her trade. It consists in cutting off the clitoris with scissors, and dressing the wound with hæmostatic powders. The children are taught to look forward to the operation with anticipation and with their precocious little minds clamor for it as the necessary condition antecedent to their marriage. It is in fact indispensable for marriages in these countries, as no man of the lower classes will consent to marry a girl who has not been circumcised. In Constantinople, under the influence of European ideas it has been largely done away with, at least as a preliminary to marriage, in the families of the government officials and others, though it is said to be common for the husband to instruct the midwife to perform the operation immediately after the birth of the first child.

The Ottoman Empire includes a wide range of nationalities with different habits and religions and climates, the temperature varying from  $46^{\circ}$  C. to  $-30^{\circ}$ . Yet the differences in the physiological condition of the women seem not to be racial, or even climatic, so much as the product of social habits affecting the precocity of sexual development. Among the Mussulmans these influences are at a maximum. From earliest childhood the conversation to which girls listen, the whole atmosphere in which they live, is permeated with the one thought of sexuality. Hence menstruation begins at nine or ten years in Egypt, Bagdad, and Arabia. In the Soudan it is even earlier. In Constantinople and its environs, the function is established among the Turkish girls at from ten and a half to twelve years, while in villages a little more remote, where the customs are more rigid, and also among Christians, Armenians and Greeks, the average date is two or three years later. Circassian slaves who remain in their native land till they are grown up, menstruate at fifteen to seventeen, while if brought when young to Constantinople and exposed to the life of the harem, they menstruate at twelve or thirteen.

In Albania, a mountainous country, where female virtue is well preserved, maturity comes late, at seventeen years. This is the case both with Christians and Mussulmans. The latter are not veiled or sequestered like other Mahometans, and their intercourse with men is on much the same terms as in our own country. The menopause comes late and they often bear children at forty-eight or forty-nine years of age.

Of course it may be true that the climatic conditions are the primary cause of the tardiness of the menstrual function, but, if so, they act through the medium of quiescent sexual emotions, and the inference from Dr. Zambaco's paper is that such a mental state is not merely the product of a low temperature, but may also result from an unstimulating character of the social atmosphere.

Mussulman women have such a horror of pregnancy as being likely to destroy their shape and beauty, as well as to cause alienation of their husbands in favor of a non-pregnant rival, that abortions are universal.

They are spoken of freely in the social and domestic circle, and performed openly and as a matter of course. For these reasons, as well as on account of the incapacity for conception of these overstimulated sexual organs, despite the opportunities afforded by polygamy, the population fails to increase to any extent. It is true that one pasha had eighty-five children by forty-four women, but with increasing poverty of the people, fewer men can afford multiple marriages and so the births among the Mussulmans are on the whole diminishing. Armenians and Greeks, on the other hand, rarely perform abortions, and Jews never.

Marriage among the Mussulman girls takes place usually before menstruation is established, namely at nine to ten years, and sexual relations are at once established. The result is various local derangements, and *very small fecundity*. One or at most two children represents the average productiveness of Mussulman women. The effect of this overstimulation of the generative function is further seen in a premature menopause, and early fading. The few women who marry late are also likely to complete their sexual existence early. In the one class of cases the sexual career is shortened through exhaustion; in the other through lack of function.

The atrophy of the sexual sense is rare enough in Turkey; we occasionally see it in one of the extremes of our own civilization, where muliebrity has perished from inanition. The Harem and the "Higher Education" may lead by widely divergent paths, to a common goal, sterility.

#### THE DOCTOR BEFORE THE LAW.

Suits for malpractice are comparatively not very common in Boston, but they seem even less common than they really are. Each physician, and particularly each surgeon, knows very well that he is liable at any moment to become the defendant in a suit for damages, and when the suit comes he accepts it as an unfortunate but unavoidable incident in his life; he meets it as his temperament and pecuniary ability enable him to do, and the matter may not be known beyond his most intimate circle. The third trial of a suit against a well-known practitioner of Boston, has just been concluded. The plaintiff has three times failed to convince a jury of her countrymen that she was deserving of remuneration for any real or fancied injury, each trial resulting in a disagreement.

The profession can but feel a deep interest in the defendant in these suits, if for no other reason than because he illustrates the relation in which the defendant in a malpraxis suit stands towards the law of the State and its exponents, the lawyers. Now our laws are framed on the principle of allowing to the humblest citizen of the Commonwealth the freest possible access to the courts, to the end apparently that neither wealth, education or social position shall afford any advantage. In accord with that principle, suits for damages are allowed to be entered without the

slightest surety on the part of the plaintiff of an ability to meet the requisite expenses, or assurance that the suit has even a pretense of honest ground to stand on. It needs only a person who has undergone surgical treatment, and a lawyer willing to enter upon such a suit on speculation or with the understanding that his fees shall be proportional to the amount of damages. In its care for the plaintiff and its anxiety to prevent oppression, the State affords every facility for such a suit and enforces no penalty for suits improperly brought. So easy is the introduction of suits that the State might almost be said to favor, if not to be a party to, blackmail. The principle that a man must be regarded as innocent until proven guilty would almost seem to be reversed in the case of a physician, so that the physician is to be regarded as guilty of malpraxis unless proved innocent. The original object of the laws would seem to be lost, and in the present constitution of society they offer facilities, which lawyers — not always regarded even as unscrupulous — are not slow to embrace, to manufacture business and oppress the supposed oppressor.

It is doubtful if any one would desire to make the doctor any less responsible for the exercise of due care in the treatment of his patients, but it would seem only proper that the introduction of suits for damages should be a little less easy.

Other countries and some States require sureties from the plaintiff before suits can be entered. We do not believe such a regulation in Massachusetts would injure the humblest citizen. The protection of the doctor certainly requires that, when a plaintiff has failed to gain a verdict after a certain number of trials, something more shall be required to renew such a suit than the mere willingness of a new lawyer to take up the case.

It is not an uncommon thing — and we know of at least one hospital surgeon so situated at this writing — that a suit should be brought against a physician which the plaintiff's lawyer straightway proposes to compromise for a certain sum, supporting such a proposition to the defendant with the effective argument that even if he (the physician) should win the case the expenses incurred would be at least double the amount of the compromise. However conscious of the justice of his cause the doctor may be, it is difficult to resist the force of such a statement; unless the doctor happens to be in the rare but fortunate position where a few hundred or thousand dollars more or less are a matter of little consequence.

It is true that corporations share with our medical brethren these perils and hardships at the hands of the law, but they are, at least, better able to support an injustice, and to recoup themselves by making the public bear the loss thus caused.

#### THE HEALTH OF BEER-DRINKERS.

MEDICAL examination of a thousand employees of the various breweries of New York and vicinity, which has for some time been in progress, under the

auspices of the United States Brewers' Association, has now been completed, and the results are to be published in pamphlet form.

The report starts out with a quotation from a work on physiology, which maintains that the constant use of beer is found to produce a species of degeneration of a great part of the organism, profound and very deceptive. Fatty deposits, diminished circulation, congestions, general disturbances of various organs, and inflammation of the liver and kidneys, are stated to be its constant results. As a result of the present investigation, this allegation is denied, and the report declares that no medical statistics have ever been produced in support of it. It is claimed that, in all ages, beer-drinking nations have been remarkable for their intrepidity, strength, and vitality, and that it was not until after the general introduction of ardent spirits into England that the enervation of the masses was spoken of in connection with intemperate habits.

With a view to ascertaining in a trustworthy manner the effects of the use of malt liquors, the physicians of the Brewers' Benevolent Bureau (which was established about five years ago for the relief of their sick employees, and for the assistance of the families of deceased workmen) were instructed to examine one thousand of these men as to their general state of health, and the condition of the liver, kidneys, and heart. Also to weigh and measure every man, to test his strength by the dynamometer, and report his age, length of time employed in breweries, and average daily quantity of beer consumed by him. Of the one thousand men, twenty-five were recorded as unsound; and of these, seven suffered from diseases of the liver, one from cardiac disease, five from diseases of the kidneys, one from emphysema, six from rheumatism, two from jaundice, two from bronchitis, and one from pulmonary tuberculosis. It is concluded, from the observations made, that the use of malt liquors, notwithstanding the large quantities habitually consumed, cannot be regarded as injurious; that the death-rate among brewers is lower by forty per cent. than the average death-rate among the urban population of the groups of ages corresponding to those to which the brewery workmen belong; that the health of the brewers is good; that diseases of the liver and kidneys occur but rarely among them; and that, on the average, brewers live longer and preserve their physical energies better than the average workman of the United States.

The statistical tables collected, however, are said to show that the majority of the men examined were under forty years of age, while a large number were in the twenties. Many of them have not been employed in the breweries over ten years, and some only from three to six years. While the record of the weight does not show much obesity among them, perhaps owing to the hard nature of the work, still the average weight is good, comparatively few weighing less than one hundred and forty-five pounds, with a proportionate circumference of chest.

We fear this is another example of the facility with which statistics in skilful hands may be made to prove any desired position.

#### UNFORTUNATE RESULT OF ONE OF PASTEUR'S "INTENSIVE INOCULATIONS."

PASTEUR seems by no means to have an easy time in his humanitarian endeavors. Not only is the protective power of his inoculations denied, even by colleagues of his in the learned societies, but it would appear that one of his recent "intensive inoculations" has resulted in the death of the patient.

It is bad enough, say the opponents of Pasteur's methods, if protective vaccination does not *protect*; it is immeasurably worse if it is liable to communicate the very disease from which it is designed to give immunity.

M. Peter, a determined anti-microbist and opponent of anti-rabic inoculations, seems to have taken a grim satisfaction in reporting to the Academy of Medicine (session, January 4th) the details of the case to which we have referred. The facts are as follows:

A young Parisian, Reveillac by name, was bitten on the finger by a mad dog, November 9th, ult. Two days afterwards he applied to Pasteur at the laboratory Rue Vauquelin, where inoculations, according to the new "intensive" method, were practised in the hypochondriac region; Pasteur's assistant going from the mild virus to the severe, and *vice-versa*, for twelve successive days, three inoculations a day being given. The health of the young man remained good for about a month, when, after premonitory pains in the cicatrices of the inoculation-punctures there ensued malaise and prostration, spasms of the œsophagus with more or less difficulty of deglutition, finally paralytic symptoms and death on the sixth day with frothing at the mouth. At no time was there any pain in the finger that was bitten, though the pain in the site of inoculation was a marked and constant symptom.

Peter, in commenting on this case, had no doubt that the young Reveillac died from paralytic rabies, a form of the disease almost unknown in man; he called particular attention to the fact that the fatal malady commenced with pains over the hypodermic punctures, which seemed to him strongly suggestive of the true cause being the inoculations, and that while there was no actual hydrophobia, and no constant sputation, yet there was difficulty of deglutition of liquids and frothing at the mouth at the moment of death.

It is regrettable that there was no autopsy on the young man, and that one important link of evidence was not furnished, viz. the induction of the disease in animals by inoculating them with portions of the medulla of the unfortunate victim.

#### MEDICAL NOTES.

—The *Medical Record*, looking upon the chances of a physician's obtaining pay for his services as dependent on the earning capacity of the head of the fam-

ily, says that there are about eleven million heads of families in this country. Estimating their incomes on the same basis as that of English tax returns, there are only about one hundred thousand families having an annual income reaching \$2,000, and only about thirty-five thousand having an income equalling or exceeding \$5,000. Out of fifty-five millions of population, forty-five millions earn \$15 a week or less.

—At a meeting of the Geneva Medical Society, writes a Swiss correspondent of the *British Medical Journal*, Dr. Goetz stated that, following the recommendation of Dr. Huchard, he used antipyrine as a hamostatic in three cases of bleeding. One was a case of severe and prolonged epistaxis in a young man suffering from hemorrhagic purpura; the second was a case of bleeding from the gums after the extraction of a tooth; and the third was a case of metrorrhagia from uterine fibroid. In the two former cases the drug was employed locally in solution; in the third, one gramme of antipyrine was incorporated in a gelatine pessary.

—The *Northeastern Lancet*, in commenting upon the zeal with which the lay press seizes upon reports of startling surgical operations, cites the following description, which was thought important enough to be cabled across the ocean to a New York daily paper. "On Tuesday of last week a slater fell from the scaffold of a house, a distance of eighteen feet, to the ground. He was carried to the St. Thomas Hospital, suffering extreme agony. No bones were found to be broken, but Wednesday, Sir William McCormac, in diagnosing the case, came to the conclusion that the bladder had been ruptured. The man was put under an anæsthetic, an incision was made into the abdomen and the diagnosis verified. The contents of the stomach and perineum were withdrawn. The bladder was drawn out, a suture made, the organs all replaced, the stomach thoroughly cleansed with antiseptics and the incision closed. The patient emerged from his insensible condition relieved of pain, and Thursday was in a comfortable condition and is now declared practically out of danger." Whether the "contents of the stomach and perineum" were put back again after being withdrawn is not stated. In this connection we note a despatch from New York to a Boston daily paper to the effect that a noted actor has had "a very delicate surgical operation" performed upon his nose. "Something like a cataract" had been growing in the right nostril for years, and was successfully removed.

#### NEW YORK.

—The Hospital Saturday and Sunday Fund, up to January 14th, amounted to \$42,796.

—The annual meeting of the Pathological Society was held January 12th, when the following officers were elected: President, Dr. T. Mitchell Prudden; Vice-President, Dr. W. P. Northrup; Treasurer, Dr. John H. Hinton; Secretary, Dr. Wesley M. Carpenter; Editor, Dr. John C. Peters.

—On the 12th of January six cases of small-pox

<sup>1</sup> See this Journal, Vol. CXV., p. 567.

were reported to the health authorities, the first that have occurred in the city, so far as known, since November 1st. Several of them were among Spanish sailors, who were found in lodging-houses, and in consequence of these cases and the recent small-pox scare in Brooklyn, a very lively demand for vaccine virus has arisen.

—The annual meeting of the New York County Medical Association was held at the Carnegie Laboratory, January 17th, when the following officers were elected: President, Dr. John Shrady; Vice-President, Dr. J. R. McGregor; Recording Secretary, Dr. P. Brynberg Porter; Corresponding and Statistical Secretary, Dr. Glover C. Arnold; Treasurer, Dr. Charles Ellery Denison; Member of the Executive Committee, Dr. Edwin Saunders.

—Measles still continue to be increasingly prevalent. During the week ending January 8th, there were reported 497 cases, with 65 deaths; and during the week ending January 15th, over 700 cases. The sanitary authorities complain that physicians in charge of cases in schools and charitable institutions do not report the disease when it first appears, and it is often not until one or more deaths have occurred from it that they become aware of its existence in these institutions. Dr. James B. Taylor, Chief of the Fourth Sanitary Division, has made a report to the Board of Health, in which he states that proper precautions are not taken as to isolation and disinfection, both in the care of measles and of diphtheria, which is also on the increase. In it he recommends that circulars should be distributed among the tenement-house population, containing suitable recommendations and advice, and calling attention to the Willard Parker Hospital on East Sixteenth Street, where measles and diphtheria are treated free by experienced physicians.

—At a meeting of the Society of Medical Jurisprudence and State Medicine, held January 13th, the subject of discussion was "How shall the death penalty be inflicted?" It was opened by Dr. N. E. Brill, who read a letter which he had received from the Committee on Capital Punishment appointed by the State Legislature, asking his views on the subject. In reply he stated that he had expressed the opinion that hanging was barbarous; quoting Dr. Hardy, who had attended numerous executions by this method, to the effect that he never in a single instance saw death occur by a broken neck. Dr. Brill considered the most humane method that of the guillotine, and said that he was opposed to electricity because dynamos were too expensive; to prussic acid because its action was indefinite and often caused violent convulsions; and to the garotte because it frequently failed. Among those who took part in the discussion were Dr. John C. Peters, who favored the garotte; Dr. McLaurie, who advocated carbonic acid gas; Mr. W. H. Russell who thought the criminal should be delivered over to a commission of selected scientists who should take his life in the interests of science; and Dr. Wood and Mr.

D. S. Riddle who believed that the present method of hanging was not necessarily brutal, and that it had more effect in deterring others from committing murder than would be the case with any of the other proposed plans.

### Miscellany.

#### HOMEOPATHY, AS REGARDED BY ONE OF ITS LEADERS.

JOUSSET, of Paris, is unquestionably one of the lights of homeopathy on the Continent of Europe. His recently published "*Leçons de Clinique Médicale*" is in some respects a model of its kind. According to this authority, the homœopath of to-day no longer affirms the mysterious potency of the globe, or the all-sufficiency of the doctrine of similars, but claims to be, in the true sense of the word, eclectic.

"Hahnemann and his pupils," he says, "pretended that homœopathy was the *whole* of therapeutics. This is a complete misconception of the case; homœopathy is but a *part* of therapeutics; this is a truth which has cost us many execrations from men in our own ranks, but is now held to be indisputable.

"The fact is, homœopathy cannot take the place of *palliative* medication; nor of *surgical* medication; nor of *antidotal* medication in cases of poisoning; nor of *parasiticide* medication, wherever clearly demanded; nor of medication by *mineral waters*, which often cures where other modes of treatment fail; nor of *hydrotherapeutic* medication; nor of medication by electricity; nor even altogether of *empirical* medication. Homœopathy is not everything, and liberal medicine must include all collateral modes of treatment."

Jousset repudiates the allegation that homœopathy is a *sect*, and affirms that it is simply a branch of medicine which has to do with the therapeutics of certain internal disorders, and not even all of these are amenable to treatment by the law of similars (for example, helminthic diseases). This same writer, who seems to have a some following in France, and may be said to represent the advanced thought of his school, gives some pretty hard blows at the advocates of infinitesimal doses, who, he intimates, have brought discredit upon homœopathy, and affirms that "the school of high dilutionists is losing ground every day, and in France, as in Germany and America, the general tendency is to employ the low dilutions."

#### THREE CASES OF SUPPURATION OF THE FRONTAL SINUS.

THREE cases of suppuration of the frontal sinus, or empyema of the frontal sinus, as they are called by the author, Dr. Borthen, are reported in the *Revue Internationale des Sciences Médicales*, 1886, No 34, *London Medical Record*, December 15, 1886. Case I. Woman, aged fifty-six. The disease began two or three years ago with headaches almost continual, and so violent as to cause vomiting. Intense coryza followed. After some time a tumor slowly developed at the internal angle of the orbit. Examination: right eye looks down and out, slight exophthalmos, right pupil about one centimètre lower than left; peculiar physiognomy. Between the lacrymal sac and the globe of the eye is a swelling about three centimètres

long, which is felt within the orbit as far as the finger can reach; fluctuation; skin normal. Slight pain on pressure below eyebrow, but no sign of cerebral compression. Movements of eye impeded, no diplopia, vertigo on closing sound eye. Thick pus escaped on exploratory puncture. Treatment: incision; evacuation of four or five teaspoonfuls of thick yellow pus; washing out with a solution of salicylic acid, and drainage, a little silver tube being left in the wound. Improvement rapidly followed, but there was still a slight discharge. Case II. Woman, aged fifty. Tumor at internal angle of orbit; no deviation of eye. Severe headaches preceded tumor. Treatment as above; incision, emptying, and drainage. Cure in a fortnight. Case III. Woman, aged thirty-three. Disseminated choroiditis and slight swelling in left orbit, internal half. Elastic tumor felt within orbit. Left eye six millimetres lower than right. Diplopia on looking to right. Headaches and violent pains in back of neck. Sleeplessness, nausea, anorexia. Treatment: skin incised, and tendon of superior oblique muscles reached and divided. Cyst punctured and washed out with a four per cent boric acid solution. Between one and two ounces of yellowish viscous fluid escaped. Drainage. An intense coryza came on some days after operation. The abscess healed, but slight diplopia persisted.

#### SALOL.

This new compound, introduced by Menck, is a derivative of salicylic acid, one atom of hydrogen of which has been replaced by the phenol group (*Pharmaceutical Journal*). Possessing antipyretic and antiseptic properties, it is hoped that it may prove of service in cases in which the salicylate of soda is badly borne. Its physical characters are those of a white powder of faintly aromatic odor, almost insoluble in water, and perfectly tasteless. In the organism, the compound becomes split up into the salicyl and phenol elements; both may be detected in the urine, which becomes very dark, as happens after the ingestion of carbolic acid, of which salol contains thirty-eight per cent. The splitting of the compound is believed to take place in the duodenum, under the influence of the pancreatic digestion. It is remarkable that no toxic symptoms appear to have resulted from the employment of salol. — *Medical and Surgical Reporter*.

#### A CASE OF HERNIA INTO THE UMBILICAL CORD.

The following case occurred at Queen Charlotte's Lying-in Hospital, under the care of Dr. Hope, and is described in the *Lancet* (Oct. 23): In the afternoon of August 25th, Mr. Harries, acting House-Physician, was summoned to the Labor Ward to see a child just born, who, the nurse said, had a swelling in the umbilicus. The child was a healthy-looking boy, who, with the exception of the rare congenital malformation described, was in every respect well developed, and weighed seven and one-fourth pounds. A hernial protrusion into the umbilical cord was found, about the size of a hen's egg. Upon examination, Mr. Harries concluded that he had to deal with a partially reducible enterocoele, with a sac, the neck of which was formed by the skin, and the fundus by the coverings

of the cord, and with the umbilical vessels spread out over the right side of it. In the absence of the visiting physician, Dr. Hope, he decided upon the following operation: Mindful of the inevitable results of separation of the cord and the exposure of the enclosed intestines, the child having been anesthetized with chloroform, the sac was opened. The contents of the sac were both large and small intestine, of which five inches of the latter were adherent to the interior of the sac. The bowel beyond, being slightly congested, was quite healthy, and was dissected off without any great difficulty. What he believes to have been the vermiform appendix was so intimately fused with the tissues of the cord as to render dissecting it off impossible; it was, therefore, ligatured with fine carbolized catgut, and divided close to the sac. After slightly enlarging the hernial opening, the whole contents of the sac were returned into the abdominal cavity. The opening was then closed with a double ligature of thick catgut, in exactly the same way as a navus is strangulated by Liston's method. The cord, with the sac, was then cut off about half an inch from the umbilicus. The operation was performed with every antiseptic precaution, and the wound dressed with corrosive sublimate gauze.

During the next fourteen days the wound was dressed twice, and each time looked quite healthy; at the end of that time, the small remaining portion of the cord separated, and the ligature was removed, the opening being firmly closed. After the operation the bowels acted naturally, and the child took its nourishment freely, some slight sickness being the only trouble. During a rapid convalescence, no symptoms of importance were manifested.

#### Correspondence.

##### AN OFFICIAL MEMENTO MORI.

Boston, Jan. 14th, 1887.

MR. EDITOR,—The alacrity with which the law-abiding physician complies with the requirement as to the notification of infectious diseases, is not enhanced by such experiences as the following:

A gentleman, of nervous temperament, was attacked with diphtheria. The diagnosis was made to the family but on account of the nervousness of the patient was not at first imparted to him. Due notice was sent to the office of the Boston Board of Health. On the following day the customary circular was forwarded from the latter office in a sealed envelope to the lady of the house, who read and inwardly digested it. Almost immediately another circular was sent to the patient himself. As he was able to read his letters his mail was sent to his room and with it the document in question. Nothing on the envelope revealing its character, he opened and read of the dreadful nature of the malady, of the precautions to be taken for disinfection, and finally of the treatment which was to be given to his body after death and of the precautions proper to be observed at the funeral. The cheerful and diverting effect of the communication can easily be imagined.

The question that suggests itself is this: admitting the necessity for public protection of notifying the householder of the precautions to be preserved, why should not the notice be sent unsealed, to be read by whoever happens to be for the time in charge of the domestic economy? Or, if the notice must be sent under seal, why is it not sufficient to send it to the one of the presumptive heads of the family who is not sick? Postage costs something. One circular is as good as a dozen and the patient cannot be depended upon to disinfect his own clothing and dis-

charges, while to impose upon him the task of planning out the details of the placing of his body in the coffin with disinfectants and the hermetical sealing of the coffin, is hardly fair to the undertaker. Yours truly, F.

#### CASE OF DEAFNESS FOLLOWING A BLOW.

2a Beacon St., BOSTON, Jan. 14th, 1887.

MR. EDITOR.—The communication from Dr. Coggin, of Salem, January 6th, relative to a case of sudden deafness following a blow, recalls a case of mine which recently came under observation.

A girl of sixteen applied at my clinic at the Carney Hospital for the relief of unilateral deafness and presented

this history: Four years before, while returning from school, she was maliciously attacked by boys, who severely snow-balled her. A hard, icy mass, thrown with force, struck upon her right ear (over the surface of the temporal bone, opposite the meatus properly.)

She immediately felt pain in the ear which continued until the next morning.

Coincidentally with the receipt of injury and persistently thereafter total loss of hearing was also complained of. No other symptoms were at any time present.

Examination of the affected ear at the time of my visit revealed nothing abnormal to the eye. Absolute loss of hearing for both air and bone conduction, as shown by ordinary and by Knapp's test, was proven. Simulation not being likely, the stethoscope test was not used.

Very truly yours, E. D. SPEAR, M.D.

#### REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 8, 1887.

Deaths reported 2,566; under five years of age 995; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 448, acute lung diseases 451, consumption 379, diphtheria and croup 191, measles 94, typhoid fever 39, diarrhoeal diseases 52, scarlet fever 30, whooping-cough 16, malarial fever 14, cerebro-spinal meningitis 13, puerperal fever six, small-pox four. From diarrhoeal diseases, New York eight, New Orleans seven, Philadelphia four, Cincinnati and Nashville three each, Boston two, Brooklyn, Baltimore, District of Columbia, Lowell, and Cambridge one each. From scarlet fever, New York 12, Brooklyn seven, Boston four, Philadelphia two, Baltimore three, Cincinnati one. From whooping-cough, New York nine, Brooklyn, Boston, Cincinnati, Lowell and Lawrence one each, Newton two. From malarial fever, New York seven, Brooklyn five, Philadelphia and Baltimore one each. From cerebro-spinal meningitis, New York four, Fall River three, Baltimore two, Philadelphia, Nashville, Worcester, New Bedford one each. From puerperal fever, Boston two, Philadelphia, Brooklyn, Baltimore, and Cincinnati one each. From small-pox, Brooklyn three, Philadelphia one.

In the 20 cities and greater towns of Massachusetts, with a population of 1,000,592 (population of the State 1,944,462) the total death-rate for the week was 22.61 against 21.77 and 20.50 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,863,817, for the week ending December 25th the death-rate was 21.5. Deaths reported 3,745; infants under one year of age 853; acute diseases of the respiratory organs (London), 436; measles 182, whooping-cough 75, scarlet fever 71, diarrhoea 40, fever 34, diphtheria 31.

The death-rates ranged from 11.9 in Brighton to 30.7 in Wolverhampton; Birmingham 18.1; Bradford 20.7; Halifax 26.0; Hull 22.3; Leeds 24.0; Leicester 19.8; Liverpool 26.3; London 19.7; Manchester 29.4; Nottingham 20.1; Sheffield 18.6.

In Edinburgh 23.6; Glasgow 22.3; Dublin 28.5. For the week ending December 25th, in the Swiss towns there were 33 deaths from consumption, lung diseases 19, diarrhoeal diseases 12, measles seven, diphtheria and croup five, whooping-cough four, erysipelas one, typhoid fever one.

The death-rates were: at Zurich 13.4; Geneva 16.2; Basle 20.0; Berne 22.5.

The meteorological record for the week ending January 8, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending	Barom-eter.	Thermometer.			Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather.			Rainfall.
	Daily Mean.	Daily Mean.	Maximum.	Minimum.	7.00 A. M.	3.00 P. M.	11.00 P. M.	7.00 A. M.	3.00 P. M.	11.00 P. M.	7.00 A. M.	3.00 P. M.	11.00 P. M.	7.00 A. M.	3.00 P. M.	11.00 P. M.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 8, 1887, TO JANUARY 14, 1887.

BAILY, JOS. C., lieutenant-colonel and assistant medical purveyor. Ordered from Department East to New York City, to take charge of the medical purveying depot in that city, relieving Captain Henry Johnson, medical storekeeper, from duty as acting assistant medical purveyor. S. O. 9, A. G. O., January 12, 1887.

BROWN, HARVEY E., major and surgeon. Granted leave of absence for six months, on surgeon's certificate of disability, with permission to leave the Division of the Missouri. S. O. 9, A. G. O., January 12, 1887.

CORSON, J. K., captain and assistant surgeon. Ordered to Fort Coeur d'Alene, I. T.

MUNN, C. E., captain and assistant surgeon. Ordered to Fort Canby, W. T.

BANISTER, J. M., first lieutenant and assistant surgeon. Ordered to Fort Coeur d'Alene, I. T. S. O. 227, Department of Colorado, December 31, 1886.

BARNETT, RICHARDS, captain and assistant surgeon. Leave of absence further extended six months on account of sickness. S. O. 9, A. G. O., January 12, 1887.

WILSON, GEO. F., first lieutenant and assistant surgeon. Leave of absence extended twenty days. S. O. 9, A. G. O., January 12, 1887.

RAYMOND, H. I., first lieutenant and assistant surgeon. Ordered for duty at Presidio of San Francisco, Cal. S. O. 127, Department of California, December 29, 1886.

IVES, F. J., first lieutenant and assistant surgeon. Granted one month's leave of absence with permission to apply for twenty-three days' extension. S. O. 1, Department of the Platte, January 3, 1887.

#### SOCIETY NOTICES.

NORFOLK DISTRICT MEDICAL SOCIETY.—A meeting for Scientific Improvement will be held at the hall of the Roxbury City Guard, 67 Warren Street, Roxbury, January 25, 1887, at 7.45 o'clock. Communications: I. "The Appearance of Intermittent Fever near the Neponset River," James S. Greene, M.D. The discussion will be opened by Harold C. Ernst, M.D., who will also demonstrate some of the forms of the Plasmodium Malarie. II. "Case of Intestinal Obstruction due to Cancerous Tumor of the Ovary," Clement W. Sparhawk, M.D. III. Exhibition of the New Barrett Chloride of Silver Galvanic Battery. S. Allen Potter, M.D. IV. "Report of Cases of Intubation of the Larynx with Exhibition of the Instruments; also, Presentation of Interesting Pathological Specimens," Wm. P. Bolles, M.D. S. ALLEN POTTER, M.D., Secretary.

THE MIDDLETON GOLDSMITH LECTURES, given under the auspices of the New York Pathological Society, at the College of Physicians and Surgeons, corner 23d Street and 4th Avenue. First Course by M. Allen Starr, M.D., Ph.D., Professor of Nervous Diseases, New York Polyclinic. Subject: "Multiple Neuritis, and its Relations to Peripheral Neuroses." First Lecture, Tuesday, January 25th, 1887, 8 P.M. "History of Multiple Neuritis, the Pathology of the Disease, its Varieties and Etiology. Peripheral Neuroses Traceable to Neuritis." Second Lecture, Friday, January 28th, 1887, 8 P.M. "The Clinical

Picture of Multiple Neuritis, Diagnosis of the Disease, Prognosis and Treatment." Members of the Profession cordially invited.

MEDICAL SOCIETY OF THE STATE OF NEW YORK.—The Eighty-First Annual Meeting of the Medical Society of the State of New York, will be held in the Court-Room, in the City Hall, Albany, N. Y., Tuesday, Wednesday, and Thursday, February 1st, 2d and 3d, 1887. Invitation is extended to all members in good standing in County Medical Societies to be present. WILLIAM S. ELY, M.D., President.

WILLIAM MANLIUS SMITH, M.D., Secretary.

#### ERRATUM.

in the JOURNAL of December 30th, 1886, p. 622, 13th line from the top of the left-hand column, in the article entitled "A Reducing Substance in Urine resembling Glucose," "proto-cateclenic acid" should have read "proto-catechuic acid."

#### DEATHS.

Died in Everett, Mass., January 14, 1887, Jonas Franklin Wakefield, M.D., M.M.S.S., aged sixty-one years.

William Perry, M.D., died at Exeter, N.H., January 11, 1887, aged ninety-eight years.

Estes Howe, M.D., died at Cambridge, Mass., January, 1887, aged seventy-two years.

#### BOOKS AND PAMPHLETS RECEIVED.

Papers on Hypertrophy of the Prostate Muscle. By Reginald Harrison, F.R.C.S. 1886. (Reprint.)

Sixty-Sixth Annual Report of the New York Eye and Ear Infirmary. For the Year ending September 30th, 1886. New York, 1886.

Elements of Static Electricity, with full Description of the Holtz and Tüpler Machines and their Mode of Operating. By Philip Atkinson, A.M., Ph.D. New York: W. J. Johnston. 1887.

Fermentation, Putrefaction and Suppuration with Demonstrations and Experiments. By H. Knapp, M.D., Professor of Ophthalmology in the Medical Department of the University of the City of New York. New York, 1886. (Reprint.)

Venous Blood Tumors of the Cranium in Communication with the Intra-Cranial Venous Circulation, especially the Sinuses of the Dura Mater. By Wm. M. Mastin, M.D., of Mobile, Ala. Read in the Surgical Section, at the Thirty-Seventh Annual Meeting of the American Medical Association. Chicago, 1886. (Reprint.)

Rest for Painful Eyes, is this Advice always good. By Julian J. Chisolm, M.D., Professor of Eye and Ear Diseases in the University of Maryland, Surgeon in charge of the Presbyterian Eye and Ear Charity Hospital of Baltimore City, etc. Read before the Baltimore Academy of Medicine, December 21st, 1886. Baltimore, 1887. (Reprint.)

A Text-Book of Pathological Anatomy and Pathogenesis. By Ernst Zeigler, Professor of Pathological Anatomy in the University of Tübingen. Translated and Edited for English Students by Donald Macalister, M.A., M.D., F.R.C.P., etc. Part II. Special Pathological Anatomy Sections ix-ix. London and New York: Macmillan & Co. 1886.

## THE USE OF ANTISEPTICS IN OBSTETRIC PRACTICE.

BY W. L. RICHARDSON, M.D.,  
Professor of Obstetrics, Harvard University.

SINCE Lister announced, in 1866, the value of antiseptics in surgical practice, the whole method of operating has been changed, and the accounts of the results daily obtained by surgeons in our large hospitals, as well as in their private practice, seem almost incredible when compared with the results reported by even those same surgeons only a few years since.

What the use of antiseptics has done for surgery it is now doing for obstetrics, and the object of this paper is to present as clearly as possible the value to be derived from their use in obstetric practice, as shown by the results obtained in the Boston Lying-in Hospital.

As early as 1847, Semmelweis declared that puerperal fever owed its origin to the absorption of decomposing organic matter, and was only a form of pyæmia. In 1860 he modified<sup>1</sup> this statement by the admission that, while still being pyæmic in character, it might also arise from the decomposition of the lochia, blood-clots, necrosed or placental tissue. With a view of preventing its invasion, he recommended the use of disinfectants. His theories and recommendations were received with ridicule, and it is only within a few years that it is admitted that in his teachings were the first foreshadowing of the true nature of this dreaded disease.

It was not until Lister, realizing the significance of Pasteur's investigations, had announced (1866) his views on antiseptic surgery, that Stadfeldt, in Copenhagen, endeavored to introduce the same method of prophylaxis in obstetric practice.

The reform has come about slowly, and the chief hindrance has been in the fact that the profession do not agree as to what is meant by the somewhat vague term, puerperal fever. The famous discussion,<sup>2</sup> which took place in the Obstetrical Society of London in 1875, on the relation of puerperal fever to the infective diseases and pyæmia, is still fresh in the memory of the members of this Society, and the result of the discussion was successful rather in bringing forward a distinct and fair statement of the various views held by the speakers, than in obtaining any expression of a positive united opinion of the leaders in the obstetric practice of that day. Nor would the history of the gradual change, which has occurred in the profession with reference to this subject, be complete without an allusion to the discussion<sup>3</sup> which took place before the New York Academy of Medicine in December, 1883, and February, 1884, the main interest in which centred in the addresses of Drs. Fordyce Barker and T. G. Thomas, the former claiming that puerperal fever was a distinct disease, developed like other zymotic diseases, and the latter pronouncing it to be unquestionably a form of septiciæmia.

There can now be no question that the weight of evidence is in favor of those who claim that what was formerly known as puerperal fever is septiciæmia, identical in its origin, course, and results with the surgical septiciæmia, which was formerly so dreaded in the sur-

gical wards of hospitals, and in the private practice of surgeons. It is, moreover, now clearly recognized that all puerperal inflammatory affections, such as ovariitis, cellulitis, metritis, peritonitis and the like, owe their origin to infection.

Those, however, who were willing to admit the truth of these statements were in doubt, until the appearance of Koch's work on bacteria, as to the probable source of the infection, and were, until Koch's monograph on the subject was made public, inclined to accept the theory long ago advanced by Semmelweis that the infection might either come from outside the patient, or owe its origin to spontaneous generation within. The announcement of the discovery of bacteria, and the important part which they played in various morbid processes turned the attention of obstetricians to what the bacteriologists were doing in the laboratories of Europe and this country, and to-day it is unquestionably admitted by many leading obstetricians that the infection in these cases must come from without.

That we may at the outset clearly understand just what the bacteriologists claim, the following brief statement, kindly furnished me by Dr. Harold C. Ernst, the Demonstrator in Bacteriology in the Harvard Medical School, must be of value:

"Innumerable investigations have shown, as one of the best established facts of medical knowledge, that the suppurative processes, and many of the acute diseases known as 'infectious,' are due to the activity of the lower forms of life known as 'bacteria.' This is especially the case with that class of affections which may be called 'maladies following wounds.'

"It may be considered proven by the experiments which have been made to determine the fact that, in the healthy human organism, there exist no bacteria. On the skin and mucous membrane they are constantly present, and in great variety, but, so long as these surfaces are intact, the most virulent organism known will do no harm. So soon, however, as there is a solution of continuity, and the bacterium is able to gain an entrance into the tissues of the body, just so soon does damage begin, provided the organism be possessed of pathogenic powers in the first place.

"The first condition necessary for the hurtful activity of bacteria to become manifest is that there should be a solution of continuity—a wound of the skin or mucous membrane. The second condition is that rather indefinite state of affairs called susceptibility of the system or of the part, such susceptibility being a lowering of the vitality, a depression of the blood-supply, or some more minute change in the cells, which it is beyond our power as yet to definitely describe.

"The classical work upon such diseases as are here spoken of is that of Koch in his 'Wund-Infections Krankheiten' ('Traumatic Infective Diseases of the Skin.'—Sydenham Society). It was this work which first made known the comparative ease with which different varieties of bacteria can be separated from each other, and which gave the great impulse to investigation which has built 'bacteriology' into a science, and has given us the precise methods by which we have learned what we at present know in regard to the infectious diseases.

"One class of these infective diseases are those of which Koch speaks in the book just mentioned, and includes those morbid processes complicating injuries

<sup>1</sup> Die Ätiologie, der Begriff und die prophylaxis des Kindbett-Fiebers."

<sup>2</sup> Transactions of the Obstetrical Society of London, Vol. XVII.

<sup>3</sup> American Journal of Obstetrics, March, 1884.

and operation wounds, that is, septicæmia, pyæmia, progressive inflammation and suppuration, and erysipelas, and, for nothing is more distinctly a wound than the lacerated surface of a uterus after parturition, puerperal fever.

"In the light of our present bacteriological knowledge, the terms pyæmia and septicæmia no longer retain their original signification, for, in Koch's words, pyæmia does not arise, as was at one time believed, from the entrance of pus into the bloodvessels, and septicæmia is not putrefaction of the living blood. These terms can now be used only as collective terms for a number of symptoms which, in all probability, belong to different diseases, that is to say, are produced by the activity of different bacteria. It is only by the observation of these bacteria that one can say with scientific exactness what special form of pyæmia, or septicæmia, may be under observation. That this is distinctly true is proven in the one direction by Koch's observation of the bacillus of mouse-septicæmia, which is fatal to house-mice, and has no effect upon field-mice or rabbits; of pyæmia, septicæmia, and erysipelas in rabbits; and in the other direction by the investigations of Rosenbach, Passet, and others, by which there are shown to be several varieties of bacteria which are active in the production of the suppurative and inflammatory processes in man.

"To what has been said in regard to septicæmia and pyæmia, puerperal fever forms no exception. In spite of Pasteur's work upon the subject, the best investigations show without a doubt that puerperal fever must be considered to be a name given, for convenience, to a group of symptoms which represent the effects of an attack upon the system by one or more varieties of bacteria. The disease is eminently a traumatic wound disease. A woman passing through the puerperal state with no untoward symptoms has never been found to have bacteria in the system, whilst those attacked by 'puerperal fever' are invariably found to have bacteria in the tissues, bloodvessels or lymphatics of the affected parts. The two conditions necessary for the entrance and growth of bacteria are present in the parturient state in a preëminent degree.

"The uterus after parturition is, like any other wounded surface, exposed to the air passing over blood and organic debris, especially exposed to putrefaction and the entrance of bacteria, whilst the profound modification of its tissues, bloodvessels and mucous membranes furnishes the second favorable condition for their growth, after they have obtained an entrance.

"The bacteria make their way in from outside. They are not born from nothing in the uterine tissues. There is no spontaneous generation about it. The vagina contains bacteria in health like the mouth, and, like the bacteria in the mouth, those in the vagina do no harm. Even in a diseased state the ordinary putrefactive bacteria do not change their character, and puerperal fever and peritonitis do not result from their presence. It is only by the entrance of the pathogenic bacteria — and sometimes of more than one variety of these — that a disturbance is produced. These pathogenic varieties are brought to the uterus. They are not there in the first place, and they are brought by the air or some other less usually suspected method of conveyance. The varieties of bacteria, which have thus far been especially connected with puerperal fever are:

"(1) Rather long cylindrical filaments, appearing especially in rapidly fatal septicæmias.

"(2) Streptococci, or micrococci, occurring in chains, common in the milder forms of septicæmia.

"(3) Diplococci, micrococci occurring in pairs, and especially where there is suppuration.

"(4) Micrococci in irregular masses.

"Any or all of these forms may be found in a single case, and there is no doubt that these will be finally resolved into a more distinct and numerous classification.

"The problem is unquestionably how to keep these bacteria out of the body. Without their entrance there will be no puerperal fever or septicæmia."

The above statement gives us concisely the present belief of the bacteriologist as to the ætiology of puerperal septicæmia. The practical results of an application of this theory, and how the problem is being solved is well shown in the clinical history of the Boston Lying-in Hospital.

This hospital, after being closed for lack of public support, was reopened January 1st, 1872. Since that time 3,337 women have been delivered, and the study of puerperal septicæmia, as it has appeared at that hospital, has been one of the greatest interest. During the first year only 160 women were confined, of this number one died, the death being due to puerperal septicæmia. From that time, however, septic infection has been more or less prevalent in the hospital, despite every effort made to prevent its occurrence. On three occasions (November 13th to December 9th, 1879, September 13th to October 30th, 1880, and May 7th to May 28th, 1883), the hospital has been closed; and, before being reopened, every ward has been fumigated and new beds provided. Whenever the hospital was thus closed there followed a period of comparative immunity from septicæmia. For a longer or shorter time the daily temperature would either be normal or much lower than usual. The freedom from anxiety was, however, of short duration, and gradually, despite every precaution we could adopt, the temperatures would begin to run higher and higher; the lochia would become offensive; the tenderness, more or less marked over the abdomen, would reappear, and soon another patient would fall a victim to puerperal fever, and another period of anxiety would begin. During the ten years preceding 1884, the hospital was rarely free from septic disease of one form or another; and, while the visiting physicians were endeavoring in every way possible to protect the patients from septic infection, they were constantly endeavoring to save the lives of those who gave evidence of septic poisoning. In looking back over the records of those years it seems wonderful what success crowned their efforts. An examination of the figures, to which attention will be called later, will show that a very low death-rate was maintained, considering the percentage of septic cases. When we consider the almost constant presence of septicæmia in the hospital a death-rate of 3.04 per cent. from septic causes, in 2,661 confinement cases, which occurred from January 1st, 1873, to December 31st, 1884, must be considered very low.

Dr. W. L. Richardson and Dr. Henry Tuck comprised the visiting staff from the date of its opening until January 1st, 1878, when Dr. A. D. Sinclair succeeded Dr. Tuck, who then moved to New York. Dr. Sinclair resigned at the close of his term of service, March

31st, 1883, and the vacancy was filled, January 17th, 1884, by Dr. Wm. E. Boardman. The office of assistant physician has since 1877 been filled successively by Drs. Samuel Howe, W. E. Boardman, and Charles M. Green. The various changes which have been made, in the attempts to rid the hospital of septicæmia, have been the results of careful study and observations on the part of the visiting physicians, and after many anxious consultations on the subject. As one septic case occurred after another every effort was made to avoid any possibility of contagion from a patient presenting symptoms of septic infection to another. Isolation of suspected cases; the employment of extra and special nurses; the assignment of different house-physicians to the suspected and to those whose convalescence seemed normal; the use of every possible precaution to insure cleanliness; the providing of individual bed-pans, syringes, etc.; constant attention to ventilation and improvement in the drainage, were among the methods adopted. Many of these changes seemed to promise improvement, which however, was always found to be temporary. From the very outset the staff were a unit in the belief, even then not generally accepted, that the views of Semmelweis were correct, and our object was to prevent the introduction of septic material from without, and the prevention of the absorption of septic material originating within the uterus and generative tract. With this latter end in view we soon began the use of vaginal injections, hoping to keep disinfected those parts especially exposed to the lochial discharge, which seemed to us one great source of danger within the patient herself. These were subsequently not unfrequently combined with intra-uterine injections, hoping thereby to also render innocuous the clots, and placental débris within the uterine cavity. All these attempts proved futile, although occasionally it did seem as though some new method of procedure which we adopted was at last to offer the long-sought-for relief. The respite was, however, only temporary, and still the mischief went on. In fact, it not unfrequently happened that, when, out of sheer despair, one of the staff would give up the use of injections, the results he obtained seemed to compare favorably with those reported by his colleague who thought himself, by continuing their use, more conservative.

In the middle of the winter of 1883 and 1884 corrosive sublimate was first tried, not only as a vaginal douche but also for the disinfecting of the hands of the attendants. A very decided improvement followed this method of procedure, and again the outlook was more cheering. Still septicæmia remained with us, but in a more modified form and the death-rate fell decidedly, as will appear from the tables which are presented with this paper.

Then came the announcement of Robert Koch's investigations of bacteria, and it seemed at last as though a better day for obstetric practice and for the hospital was coming. Garrigues, in New York, had adopted the new theory, and had already made public the efforts which he was making in the New York Maternity, and the results he was obtaining. We determined to change our whole system.

Heretofore, following the theory advanced by Semmelweis, we had been trying to prevent the introduction within the system of those elements which, whatever they were, would produce disease, and also to prevent those elements, when generated within the system, from

doing harm. In other words, we had been dreading and fighting attacks from within, as well as from without. We now determined no longer to fight a foe within, which existed only in a false theory, but to accept the theory of the bacteriologists, and prevent the entrance of the foe from the front. If, as we believed, the investigations of the bacteriologists had led to a correct theory, namely, that puerperal septicæmia was the result of the introduction from without of bacteria within the body of the patient, and that it was impossible for a case of septicæmia to be autogenetic in its origin, the problem of prevention became at once a comparatively simple one. How best to solve the details of the problem was, of course, a matter to be determined by experiments.

The vaginal injection during the convalescence, from which, when we adopted its use, we had hoped so much, now seemed to us to be possibly, in one way, a source of as much harm as good and was therefore discontinued. We endeavored to disinfect, as thoroughly as possible, the generative tract at the beginning of labor, lest the dreaded bacteria might already have found a resting place, and was only waiting an opportunity to infect the system, wherever a break of continuity should admit of its entrance; during the progress of the labor, to never allow the patient to be touched by the attending physician or nurse without the use of disinfectants; and the adoption during the convalescence of a disinfected pad, which should still further act as an effective barrier to the entrance of these dreaded germs, until the period of danger was passed.

Stadfeldt,\* in Copenhagen, had, as early as 1870, recommended in obstetric practice the use of carbolic acid as a disinfectant; and Tarnier, in a paper read (1881) before the International Medical Congress, advocated the use of the bichloride of mercury. Other practitioners subsequently recommended other disinfectants, such as thymol, chloride of lime, permanganate of potassium, biniodide of mercury, and many others less known and less valuable as disinfectants. In the Boston Lying-in Hospital, we had for many years used carbolic acid, and since 1884 we had been experimenting with the corrosive sublimate. The relative expense of the two, and the admirable results which Garrigues had already reported,<sup>†</sup> induced us to select the latter as the disinfectant to be used. A pad, somewhat similar to that introduced by Garrigues into the New York Maternity, was adopted, except that we substituted what is known as absorbent waste instead of oakum, experience having taught us that the smell of oakum was itself deceptive, and had often disguised the odor of the lochial discharge.

The method which we adopted in the fall of 1885 was as follows:

On her admission to the hospital, if time allows, the patient is given a bath. In every case the genitals and the surrounding parts are washed with a solution of the bichloride of mercury ( $\frac{1}{5000}$ ). A basin containing the same solution and a nail-brush is placed on a stand side of the bed. The physician and nurse in attendance disinfect their hands every time they have occasion to examine the patient or touch the neighborhood of the vulva. The examining finger is smeared with an ointment made of one part of the oil of eucalyptus and seven parts of vaseline. A vaginal injection

\* Stadfeldt. *Des Maternités*, Copenhagen, 1876.

† New York Medical Record, December 29, 1885.

tion of the corrosive sublimate solution is given at the beginning of labor, and this is repeated, when circumstances permit, at the end of the first stage. As the head distends the perineum and is expelled, the parts are kept clean, when occasion requires, by the use of charpie dipped in the mercurial solution. After the birth of the child, no undue haste is made to bring about the expulsion of the placenta. This is effected, if possible, by Crede's method of expression, great care being taken not to introduce the hand within the vulva, if such a procedure can be avoided. The perineum is carefully examined, and if there is sufficient laceration to require sutures, the parts are washed with the corrosive sublimate solution, after which the edges are brought together by means of carbolic cat-gut sutures, some powdered iodoform being subsequently applied over the seat of the laceration. The vaginal injection is repeated, and the antiseptic pad is applied, being pinned at the four corners to the abdominal binder by means of safety-pins.

During the convalescence the pad is changed as often as occasion requires, the nurse taking care to thoroughly disinfect her hands before removing the pad. Each time the pad is changed, the parts around the vulva are sprayed with the mercurial solution by means of a hard-rubber sprinker, made by the Davidson Rubber Company to fit their syringes, which are the ones used in the hospital. It is usually necessary to change the pad during the convalescence about as frequently as it was formerly necessary to change the napkins which the patients wore before the pad was introduced. If it is necessary to use a catheter to empty the bladder, that instrument is, of course, to be disinfected, as well as the hands of the person using it. Care is also taken, before introducing the catheter, to wash the parts in the neighborhood of the meatus with the disinfectant, in order to avoid the introduction of blood, vaginal or uterine discharges within the urethra.

The use of the antiseptic pad is continued until the patient sits up, or until all danger of septic infection has passed. Whenever the mother has given birth to a putrid child or a partially-decomposed placenta, an intra-uterine injection of the corrosive sublimate of the same strength is given at the close of the labor, in addition to the vaginal one already alluded to. Should it be deemed advisable to give an intra-uterine injection, it is safer, after washing out the uterine cavity with the mercurial solution, to ~~then~~ without removing the nozzle of the syringe, inject a few ounces of a solution of carbolic acid ( $\frac{1}{2}\%$ ) of the same temperature ( $112^{\circ}$ ). By this method, any danger of mercurial poisoning (which sometimes, though rarely, follows the use of corrosive sublimate as an intra-uterine injection) is avoided.

In case it is found necessary to use instruments during the delivery, care is taken to disinfect them by means of a solution of carbolic acid ( $\frac{1}{2}\%$ ). The same solution is used for the needles, needle-holder, etc., which may be required for sewing up any perineal laceration. Carbolic acid is used in these cases, in preference to the bichloride of mercury, on account of the corrosive action of the latter on the instruments. If, for any reason, it is necessary to introduce the hand within the uterine cavity, great care is taken to thoroughly disinfect the arm, as well as the hand of the operator.

The antiseptic pad is made as follows: A strip of

Canton flannel ( $19 \times 4\frac{1}{2}$  inches) is placed upon a table, with the soft side uppermost. On the centre of this is laid a piece of carbolic cotton ( $11 \times 4\frac{1}{2}$  inches), about half an inch in thickness when not compressed. Over the centre of this is a piece of oiled muslin ( $9 \times 4$  inches). On this is placed the pad itself, which is made of what is known as absorbent scrap or waste done up in cheese-cloth, and of a size sufficient to cover the oiled muslin, and about half an inch in thickness, before it is wet or compressed. This pad, before using, is dipped in a solution of corrosive sublimate ( $\frac{1}{2000}$ ) and dried. Whenever a pad, with its binder, is removed and a fresh one substituted, the old pad, including the Canton flannel, oiled muslin, etc., is burnt up.

Formerly, the patients were delivered indiscriminately in different wards, with a view of scattering the patients through the hospital, in order that each nurse might have an equal experience in the care of the cases. Since, however, the new method has been introduced, the labor is kept in one ward until that is filled up, and then passed to the next, the patients, as a rule, remaining in the ward in which they are confined until their discharge from the hospital. As soon as a ward becomes vacant, it is thoroughly fumigated by the use of sulphur-fumes, and the walls are washed down with soap-suds and carbolic acid. The weather permitting, the windows are opened and the ward thoroughly aired before it is again opened for the reception of patients. In case any patient has been confined in the ward, whose convalescence has been in the least suggestive of septic infection, the walls, after being thoroughly washed with soap-suds and carbolic acid, are wiped over with a solution of carbolic acid ( $\frac{1}{2}\%$ ).

Since the fall of 1885 the above has been the method in which antiseptics have been used in the hospital. The results have demonstrated, beyond the possibility of a doubt, the great value of such prophylaxis. In critically examining the results it must be remembered that the drainage, ventilation and hygienic condition of the hospital have been unchanged; the nurses, house-physicians, and medical staff are virtually the same, and the patients are from the same class in the community as before the introduction of the present method of conducting the cases. The only change is in the manner of using the antiseptics during the delivery, and the more frequent disinfecting of the wards than was formerly the custom.

During the present year there have been three deaths, but in no case could the fatal result be ascribed to septic infection, as is readily seen from the following brief record of the cases:—

CASE I. (Service of Dr. W. E. Boardman.) A. S., single, aged twenty, primipara, entered the hospital January 28th. Nervous, despondent. Rigidity of os. Early escape of liquor amnii. Labor, preceded for ten days by an almost constant aching pain in lower abdomen and sacral region, lasted over thirty hours. Girl, weighing seven and six-tenths pounds, delivered alive with forceps. Patient died three hours later of shock and exhaustion.

CASE II. (Service of Dr. Wm. L. Richardson.) M. G., married, aged forty-two, twelfth pregnancy, entered the hospital November 6th, being about six and a half months pregnant. For two months previous to entrance, headache, partial blindness, vomiting and diarrhoea. On entrance, stupid, speech unintelligible.

Urine scanty, containing albumen, blood, fine granular and hyaline casts. Manual dilatation and version. Male child, delivered, weighing three pounds, which lived a few moments. Pilocarpin. Patient remained unconscious and died eighteen hours after entrance.

CASE III. (Service of Dr. Wm. L. Richardson.) L. M., married, aged twenty-four, primipara, entered the hospital November 20th, about eight and one-half months pregnant. Three convulsions before entrance. Unconscious, breathing stertorous. Urine scanty and containing albumen, blood, coarse and fine granular and hyaline casts. Cervix rigid. No signs of labor. Manual dilatation, attempted by Dr. Richardson, unsuccessful. Barnes' dilators failed. Male elastic catheter introduced with a view of inducing labor. Convulsions continuing, visiting physicians unavoidably absent, Dr. C. M. Green, failing to effect manual dilatation, incised the os uteri and delivered, by version, a still-born male child, weighing six pounds. The mother died during the extraction.

With a view of presenting as clearly as possible the results of the various attempts to protect the patients from septicæmia the two diagrams accompanying this paper have been prepared. These diagrams are the result of an analysis of the temperature charts and clinical records of all the cases (1780 in number) which have occurred in the Boston Lying-in Hospital during the last six years.

The first diagram, based on an examination of the temperature charts, gives the percentages of the maximum temperature of each patient during the convalescence.

The second diagram is the result of an examination of the same charts, combined with a reference in some cases to the clinical records and shows the percentages of the number of normal, doubtful and dangerous cases.

With very few exceptions all cases in which the temperature did not exceed 100° are classified as normal; while those whose temperature rose between 100° and 102° are considered as doubtful; all others being classed as dangerous. The few exceptions made in this classification are in those cases where the temperature may have exceeded these arbitrarily selected limits, but where such rise was only transitory and due, as shown by the clinical record, to some clearly defined cause, such for example as mental emotion, indiscretion in diet, etc. In the diagrams and tables the nearest whole percentage has been used, with a view of avoiding fractions as far as possible. An examination of both these diagrams shows very clearly the poor condition in which the hospital was during the time when only a comparatively few patients escaped septic infection.

According to Schröder and Lusk 100½° may fairly be taken as the physiological limit of the puerperal state. Taking 100° however as the standard, simply because the percentages in these tables have been figured regardless of fractions of degrees, it will be seen how gradually a change for the better was brought about until the adoption of the present method of prophylaxis.

Year	Percentage of cases not over 100°, 8	Over 100°, 88.
1881	19	81.
1882	35	73.
1883	53	46.
1884	56	44.
1885	77	22.

The experience of the New York Maternity has

been in many respects so strikingly similar to that of the Boston Lying-in Hospital, that a table showing the results in the two institutions cannot fail to be of interest. In the New York Maternity, as appears from this table, puerperal septicæmia was making sad havoc among the patients until October 1st, 1883, when Dr. H. J. Garrigue, one of the Visiting Obstetric Surgeons, determined to adopt the method of prophylaxis\* which, without any material change has continued in use to the present time, and which is in the main identical with that used in the Boston Lying-in Hospital, since October, 1885.

The results which followed this use of antiseptics in the Boston Lying-in Hospital were so satisfactory that on December 3d, 1885, when I attended, in her first confinement, the wife of a physician in this city I determined to use the same general method of procedure. From that time to the present I have always adopted this form of practice. The results have been as striking as in the hospital. With the single exception of a patient who was delivered April 17th, 1879, and died a few days later of puerperal septicæmia I have been fortunate enough to escape in private practice any fatal results from this dreaded disease.

The convalescence, however, since this use of antiseptics has been free from offensive lochia; there has been a marked freedom from any tenderness over the uterus or its appendages; less complaint has been made of after-pains, and the general range of the temperature has been much lower, rarely exceeding 99°. The labor is conducted the same as in the hospital, except that the vaginal douche at the end of the first stage is omitted, nor is a bath of course essential at the outset. All the nurses who have recently graduated from the Lying-in Hospital are familiar with the methods of making the pads and providing the necessary arrangements. Many also of the older graduates have come back for a visit to the hospital and for instruction as to the new method of procedure. In all cases, however, a few words from the physician beforehand will be sufficient to enable the nurse, however inexperienced she may be in the use of antiseptics, to obtain the materials, properly make the pads, and carry out the details of this method. Until recently it was necessary

\*Antiseptic Midwifery, H. J. Garrigue, 1886.

to buy the various articles of which the pad is composed at different places, but Messrs. Leach and Greene now keep all these materials in stock, and have also the pads all prepared and done up in packages of a dozen, for those who do not care to take the trouble of making them. It is only necessary to dip the pad itself in the corrosive sublimate solution, and subsequently to dry it. In the antiseptic tablet, manufactured by John Wyeth & Brother, of Philadelphia, after a formula of Dr. Charles M. Wilson, we have a very convenient form of ordering the mercurial solution. The addition of one of these tablets to three pints of water at once furnishes us with a solution of the required strength. For an average case between four and five dozen pads are sufficient. Should the patient prefer to make the pads the following materials will be required: four yards Canton flannel, five yards cheese-cloth, three-fourth yard oiled muslin, one pound absorbent cotton waste, one pound carbolized cotton. In either case fifty antiseptic tablets will be sufficient.

The discovery of Koch and the investigations of other bacteriologists have produced practical results, which must be apparent to any one familiar with the reports of many of the Lying-in Hospitals in Europe and America. The adoption of similar methods of prophylaxis in private practice can only be a question of time. The germ theory, upon which this practice is founded, is new and to a great extent contains much yet to be investigated. Sufficient, however, is known to have already produced results which demonstrate the fact, that, to a further study of the germ theory, we must look for still greater advances in that preventive medicine, which is so rapidly reducing human morbidity as well as human mortality. The advocates of the use of antiseptic obstetrics in private prac-

tice will unquestionably meet with opposition on the part of many, who will quote their own experience as evidence that puerperal septicæmia is a disease of extreme rarity in private practice. This may be true, but judging from my own observation in consulting-practice I am convinced that it is not as rare as would appear from the statistics of private practice which so frequently appear in our medical journals or in the records of medical meetings. Many physicians do not follow up their cases, and the number of visits after the birth of the child is frequently very limited. Cases which thus pass from observation are considered successful by the physician in attendance at the delivery, though it may happen that subsequently they are attended by some other physician during a long and troublesome, if not fatal illness. A somewhat extended dispensary service has taught me the truth of this observation.

Kucher, in his admirable book on "Puerperal Convalescence and the Diseases of the Puerperal Period," reports that the statistics of life insurance companies<sup>2</sup> show that of 2,182 insured women, 197 (9.03 per cent.) died from puerperal causes, and that statistical tables indicated that nearly seventy-five per cent. of the deaths during childbed are due to puerperal fever. Even if the danger from septic infection be as slight, as some would have us believe, should we neglect to use every known precaution to reduce even that danger to a minimum? The experience of those who have investigated this subject and practically tested this method of treatment has demonstrated, that absolute asepsis means absolute freedom from puerperal septicæmia, and that the occurrence of puerperal septicæmia means the absence of absolute asepsis.

# SOME NOTES ON THE TREATMENT OF PHTHISIS IN COLORADO: WITH ILLUSTRATIVE CASES.

BY SAMUEL A. FISK, A.M., M.D., DENVER, COL.

In presenting this subject for the consideration of the meeting this evening, I am well aware that it is so vast a one that we can hope to touch upon but few of the prominent points and must necessarily leave much of the details unconsidered; and further, that the class of cases to be considered are so common with us, by virtue of our becoming a refuge for those affected with pulmonary disease, that the thoughts to be presented may seem trite and threadbare. In regard to this latter point, if indeed it be necessary to urge any extenuating reason for presenting this subject, I can but say, that while I have frequently conversed with one doctor and another in regard to the cases of phthisis under his observation I have never, during a six years' residence in this State, listened to an article upon the subject in either the local or State society,—due, no doubt, to the fact that common-place and everyday events are deserving of but little notice, and that we see so much of phthisis in its several stages of decline, arrest or cure, that it may seem as though there were but little of interest to be said on the subject.

However, as I look around the assembly and see the number amongst those of us present who I know have come to this State on account of some pulmonary difficulty, and who having found a restoration of health, have said, "Here am I and here will I abide," I cannot feel that the discussion will be devoid of interest and I am conscious that the utmost that I can attempt is to formulate a few ideas which will serve as a theme for the discussion.

There will be found those amongst us who will agree with Flint that: "There is no such affection as a non-tuberculous pulmonary phthisis," and on the other hand there may be those who hold to Niemeyer's theory, backed by the researches of Virchow, that phthisis is frequently catarrhal in origin. Some will believe that Koch and others have proven beyond a doubt that the *bacillus tuberculosis* is the unfailing cause of phthisis pulmonalis, and others are still holding their decision in abeyance.

It is not my intention to even touch upon these disputed points, but rather to treat of the subject in terms which, we shall probably all agree, give evidence of pulmonary phthisis and to cite cases as types and by way of illustration of what I wish to say of the selection of cases to which our climate is adapted; the kind of cases from which we may expect the most favorable results; the precautions that must be observed in order to obtain these results and considerations of a like nature.

We recognize, for instance, a stage of incipency in phthisis characterized by loss of strength and weight, cough, more or less difficulty in breathing, more or less expectoration of a glairy mucus, fever, increased frequency of the pulse, night sweats, hemorrhages, and the physical signs of dulness on percussion, broncho-vesicular respiration, bronchophony, prolonged expiration, and it may be the development of fine subcrepitant râles.

It is not necessary that all of these symptoms should be present in order to justify a diagnosis, any more

than it should be insisted absolutely that typhoid fever can never exist without diarrhoea or petechiae.

Experience has demonstrated that the progress of such cases, if remaining in a moist, low climate, where there is a small percentage of sunshine, is from bad to worse. These are they who form the recruits to the annual mortality of 100,000 persons who die of consumption in the United States. On the other hand, we of Colorado can certify to the vast numbers of recoveries that have occurred amongst invalids coming to this State with symptoms indicative of incipient phthisis.

We have among our citizens not a few who were sent to us because of a consolidation of limited extent at one apex, evidenced by dulness on percussion, a prolonged and blowing expiration, the development of a few fine subcrepitant râles, it may be produced only by cough with deep inspiration, the physical signs being attended by loss of strength and weight, night sweats, cough, especially on going to bed and on arising in the morning, or at least by a constant hacking, and more or less expectoration of a glairy mucus. Such cases may or may not have had one or more hemorrhages and they may or may not have a family history of an hereditary phthisical taint. Although it cannot be claimed that a residence in our climate is an unfailing cure in such cases, yet the numbers of cases is so great as to warrant the assertion that the Colorado climate is admirably adapted to persons suffering from phthisis in its early stages.

Let me cite a few cases by way of illustration and selected with reference to the varying conditions existing.

CASE I. On the 26th of October, 1884, I examined a young man, twenty-one years old, who came from New England with a history of having lost a brother (twenty-two years old) and a sister (sixteen years) of consumption, and having another sister (sixteen years old) sick with consumption — of which disease she died over a year ago. He had always shown a tendency to colds; and in order to throw off this tendency, he had been to Florida, and had also been on a sailing-vessel to Japan. When I examined him he was troubled with a dry, hacking cough, as though there were a constant irritation in his throat. He had indigestion, flushed cheeks, elevation of temperature in the afternoon, rapid and excitable pulse, and a physical examination revealed: expansion, two and one-quarter inches; percussion dull at left apex; auscultation, prolonged and whispering expiration at left apex, with a click or two on cough, with deep inspiration.

To-day this man is entirely free from any cough or hectic. He is living at an elevation of about 8,000 feet, and doing a man's work, and seems well in every respect.

CASE II. On May 1st, 1885, I examined a young man, twenty years old, who had been a jeweller in New York, and who gave the following history: No hereditary taint; he himself had always been healthy, save for a nasal catarrh. In June, 1884, he caught a bad cold, had night sweats constantly, and lost flesh and strength. When I examined him he was very short of breath; coughed, especially in the morning, raised a thick, tenacious sputum, and his voice was decidedly husky. Physical examination revealed dulness at both apices, a broncho-vesicular respiration, bronchophony, and the presence of some fine râles at the left apex.

<sup>1</sup> Read before the Denver Medical Society, December 7, 1886.

This young man has been at work as a machinist almost constantly since he came here. His cough has disappeared; his hoarseness has almost gone. He has gained fifteen pounds in weight. He is strong and well, and shows but little evidence of ever having had any pulmonary difficulty.

The two foregoing cases are average ones; we could find the like on all sides. The one showed signs of incipient phthisis, complicated with a strong taint; the other of incipient disease of both apices, without any taint. Neither of them was hæmorrhagic. As an illustration of the latter condition, let me cite the following:

CASE III. Came to Colorado some nine years ago with a prognosis from an eminent specialist in the East that he could not live six months, because of his hæmorrhagic tendency. For five years he was entirely free from hæmorrhages, and for a good part of the time was able to earn his own support. Finally, in March, 1882, after a hard day's work, he was taken with a hæmorrhage, which was followed by one or two more. He was kept perfectly quiet for several weeks. When he was able to be about again, he one day, about the middle of June, rode horseback twenty-five miles in the afternoon. The next morning he rode the same distance back. The day following he took a long journey by rail, and the day following that he rode horseback some thirty miles. On this followed a slight hæmorrhage, and in about a week afterwards, after some indiscretion, a very profuse hæmorrhage, for which I was called to see him. This was in Estes Park, at an elevation of 7,500 feet. There was some consolidation at the left apex. I speak without notes. I could not find any trace of cavity, and there was no hereditary taint.

Under care, he recovered, so that he gained strength and weight wonderfully. Was able to ride long distances before the summer was over, and since then he has rid himself of his cough; has lived in Leadville, an elevation of over 10,000 feet; went East for several months one summer and autumn, and seems to be in a fair way of living to a good old age.

It may, however, be argued that this is an unusual case. While I think that many like it could be cited, perhaps the following will come nearer being the typical one:

CASE IV. Was one of the few survivors of the "City of Columbus," that went down in Vineyard Sound on her way from Boston to Savannah in the winter of 1884. He, at that time, contracted a cold which clung to him, until in March of the same year he had a hæmorrhage. This was followed by night sweats, loss of weight and strength, and dyspnoea. In August he had a second and profuse hæmorrhage. I examined him August 24th, 1884, and found that his father had died of consumption at the age of thirty-two years. In other respects his family history was good. At the time of examination he suffered from shortness of breath, cough, especially in the morning, a considerable thick, yellowish expectoration; and on physical examination, I found an expansion of two and one-quarter inches, dullness at the right apex, and a few fine, moist râles at the same apex. I have now lost track of this patient, but for many months he gained in every particular, and had had no recurrence of the hæmorrhage.

There are cases that are not so far advanced as those cited, where speedy and great good is received

by coming to our climate. By way of example, let me cite the following:

CASE V. A young man about entering college. Age, twenty-one; comes of a long-lived race. In June, 1886, noticed an invariable morning cough, which grew worse in July. Expectoration greenish-yellow and tenacious. Loss of strength, but no night sweats.

Physical examination made September 18th, 1886. Expansion, three inches; percussion slightly high at the right apex; auscultation, fine, moist râles developed with cough, and deep inspiration over supra-clavicular and supra-spinous regions on the right. Pulse, 40, temperature 99.4°.

This young man has so far recovered that he has, within a few weeks, taken out a life-policy in one of the best insurance companies in the country, the examiners for which are members of this Society.

When the disease becomes more advanced, and larger areas of lung tissue than the mere apex became involved, even then, in a good number of cases, the results are excellent from coming to Colorado. A most marked instance is the following:

CASE VI. A young man, aged twenty years, living on the New England coast, and working in an office, contracted a cold in the early months of the winter of 1881-82, which hung on him until he came to Colorado in March, 1882.

At that time I found family history good. Had lost nineteen pounds in weight; lost strength. Was having constant cough; expectoration muco-purulent and abundant. Marked shortness of breath; hectic. Physical Examination: Percussion note high over the right upper lobe, and abundant fine, moist râles over the same.

His digestion was excellent, and his recuperative powers great. Of all the patients that I have had under my care, I have never had one so rational, nor one who took such good care of himself as he. From the minute that he put foot in Colorado, he began to improve. Life in the open air, sleeping in a tent, and work on a ranche in the San Luis Park made a broad-chested, muscular, powerful man of him, and to-day he is living, in perfect health, in one of the most trying climates on the globe, that of the eastern coast of Massachusetts.

There are cases, where the development of phthisis may well be feared from the fact that a pneumonic product is slow in being resolved, or a pleuritic affection, with adhesions, may produce an irritation which will result in fibroid phthisis. Such cases have been found to do admirably in our climate.

The following illustrations will serve as types.

CASE VII. A young medical student, in Boston, of excellent family history, but with a personal history of two previous attacks of pneumonia, was put to bed early in April, 1880, with a rapid pulse, a temperature of 104.5°, pain on the left side in the region of the nipple, cough, and expectoration which never became "rusty"; also night sweats were present. There was found to be a limited area of dullness near the left nipple, and râles. The diagnosis was made of an acute catarrhal pneumonia. The trouble proved to be asthenic. After four weeks he was sent into the country, then into the hills of Maine, and afterwards into the White Mountains. Although he gained in strength so that he played tennis, climbed mountains, and did all sorts of foolish things, yet the consolida-

tion remained and was accompanied by a constant cough and abundant muco-purulent expectoration. In October of that year he was sent to Colorado, being adjudged an "unfavorable case." For two years he practised his profession, in a desultory way, and lived constantly in the open air out on the frontier. In the fall of 1882, he saw the late Dr. Austin Flint, who examined him then for the first time, and pronounced one lung as good as the other, and to-day, or rather this evening, he is the reader of this paper.

CASE VIII will illustrate the pleuritic condition of which I spoke.

Mr. X., of the Massachusetts coast, aged twenty-eight years and with a family history of having lost a sister, a maternal uncle and the maternal grandfather of consumption, was attacked in September, 1884, with pleurisy of the left side, which confined him to the house for three or four weeks. He came to Colorado in November, 1884, and was having night sweats. He had lost flesh and strength, but he had never had a hemorrhage.

I examined him in March, 1886, and found that he was coughing a little, was raising a slight amount of thick, tenacious sputum, and that, on a physical examination, there was a slight area of dulness with some fine rales at the base of the left lung, in the axillary line. The signs were aggravated in his case by an irregular life. He has since then done admirably and went East for the summer. I have not seen him since.

But, gentlemen, I will not weary you by the citation of cases that serve only as familiar types to you all. There is probably not a practitioner here but that could match any one of these that I have presented by many others from his own experience. Before, however, proceeding to some general remarks on the treatment of the disease, I wish to record a case of growing recovery from a chronic laryngitis, consequent upon a phthisical condition.

CASE IX. Bostonian, thirty-five years of age, cor-netter. Noticed tickling in his throat and a dry hacking cough in August, 1884, which continued until January, 1885, when he had a general breaking-down, but has never had a hemorrhage. In February, 1885, he went to Minneapolis. He spent the summer months in the pine-woods of Wisconsin and came to Colorado in November of 1885. He used, he says, to expectorate a teacupful of muco-purulent sputa every night, and he had fallen in weight from one hundred and thirty-five to one hundred and twenty-five pounds.

About December 1st, 1885, he had lost his voice. He could only speak in a whisper that could be heard only a few feet, when about September 1st, of this year, under the stimulus of a life out-of-doors day and night, and local treatment, to tone up, if possible, the dilated bloodvessels of the parts, he recovered tone in his voice and to-day, absolutely free from cough and expectoration, in possession of strength so that he can do a hard day's work, and with a voice somewhat husky, but strong enough, as he says, to be heard half a mile, he is anxious to go back to Massachusetts and spread the good tidings of the efficacy of the dry, bracing, Colorado air in the cure of many phthisical conditions.

It is not to be contended that our climate is the best and cure all. We can number too many cases that have come in the advanced stages indicated by emaciation and cavity, and have speedily given up their lives

here, to feel that it is sanative in all phthisical conditions. To be sure we can cite cases that have, even in these stages, prolonged life for months and years; and yet, most of us will probably agree in the assertion that this rare, elevated air is contra-indicated in the so-called third stage of phthisis.

Moreover, in every case, be the trouble great or be it little, the advice and direction of those experienced in the treatment of the disease are aids.

We know, perfectly well, that some cases will do well in one portion of our State and others in another. We know that it is essential to give directions in regard to all hygienic measures, to specify in regard to the minutest details of life, even to make inquiry into the methods of clothing, the diet, amount and manner of exercise, the sleeping accommodations, the hours of sleep, etc.

We know that it is a mistake for persons to come to Colorado and shut themselves up in an office or with indoor work. We can each of us recount the sacrifice of life that has been made, in case after case, by an undue haste to be at the work of life again.

If there is any one thing that we should harp upon to our patients, it is caution. Caution not to exercise too much, especially at the first. Caution not to sleep in an illy-ventilated room, nor in a draught. Caution not to catch cold. Caution not to keep late hours, not to smoke too much or perhaps not at all, and caution not to do this thing or that thing. An exceeding watchfulness is the price of a recovery, and if we expect to obtain good results we must be specific in our details to a degree that it is often wearisome. As I look back upon my cases, I can recall a fatal termination due in all probability to a fishing excursion; another due to a desire to earn a living in a counting-house; another to undue exercise in climbing hills while surveying; another to taxing the strength too greatly by lifting, etc. Even in those cases in which a recovery eventually occurs there are apt to be some set-backs. An imprudence in playing tennis, or riding horse back, or in dancing, or taking part in theatricals, not to speak of the more earnest walks of life, not infrequently causes dangerous and trying exacerbations of the disease.

It sometimes happens that a mental despondency will interfere in cases that, so far as the symptoms, history and physical signs are concerned, warrant a favorable prognosis. I recall one marked case where a young man, having some consolidation at the right apex, which extended down into the upper lobe on the right, was so depressed by the death of his wife, which happened while he was *en route*, and knowledge of which was kept from him for some time, that he sank steadily although his physical condition warranted at least a guarded prognosis.

The one thing that I insist upon in the cases just come to our climate, is rest. So much do I harp on it, that I often tire of the repetition. I urge comparative inactivity for some time after coming here. How often do I tell such patients to exercise short of anything like fatigue, to walk but moderately, and to spend most of the hours of sunshine in some corner on a veranda, where they will be sheltered from the wind and be basking in the sun. The altitude of one mile above sea-level gives the diseased and unaccustomed lungs all that they can properly attend to, without putting upon them the additional work caused by over-exercise.

As regards medication I have but little to say. The treatment is *pro re nata*, so far as drugs are concerned. My rule is to give absolutely none, unless there are very decided and positive contra-indications. My belief is that rules that hold at sea-level with reference to alcoholics do not appertain *in toto* at this elevation. It is often a nice point to determine whether to continue the daily doses recommended by eastern advisers.

Where the stomach will digest it, I find cod-liver oil, either pure, or in an emulsion, of great advantage, and yet even this should be exhibited with caution. In perhaps the larger proportion of cases my advice is in regard to general regimen rather than in regard to the administration of drugs.

Gentlemen, the large percentage of our population that is composed of the invalid class who have found a recovery in this climate and have pitched their tents here, is the most potent argument in favor of its efficacy. We know that we are blest with the great climatic conditions of a dry atmosphere, a rare and pure atmosphere, an amount of sunshine that is unrivalled and high sun-temperatures.

We know that these factors, the absence of endemic phthisis, and a dry soil are strong arguments in favor of this being a curative climate. We know, further, that an out-of-door life is possible during more hours of the day, and during more days in the year, in this climate, than in almost any other on the face of this earth; but the most conclusive testimony to be found, as regards the curative influence of a life in Colorado, in cases of phthisis pulmonalis, is in the thousands upon thousands of people who can, in their own persons, bear testimony to the fact.

At least one hundred thousand people in these our United States die every year at the hands of this fell disease.

Does not our duty, not to ourselves but this large invalid class, compel us to proclaim far and wide, the efficacy of the cure to be obtained in the Rocky Mountain region; to point out the cases that can reasonably expect a benefit; to implore the eastern doctors not to take us as a *dernier resort*, and, finally, to devote our best energies to assisting nature and climate when once the invalid is in our midst?

"It is an absurd supposition that any climate exerts a specific influence in arresting phthisis," writes Dr. Flint, in his article in "Pepper's System of Medicine." Whether this statement be true or not, we know, by proof positive, that Colorado climate, assisted by wise direction, and cautious living, has been curative in cases without number that would probably have proved fatal under their old surroundings and conditions, and we can but argue from this, that what has been done can be done again, and that like conditions and like causes will produce like results in the future as they have in the past.<sup>1</sup>

—The Board of Health of Syracuse, N. Y., has condemned the High School building, on account of defective plumbing. It was built in 1869, at the cost of \$100,000.

<sup>1</sup> Exception was taken in the discussion, to the remark that "most of us will probably agree in the assertion that this rare, elevated air is contra-indicated in the so-called third stage of phthisis, and it was claimed that the amount of lung-tissue involved was more of a contra-indication than the stage of the disease. There is truth in this view; and what is perhaps intended by those maintaining these views is, that Colorado is not the place for "forlorn hopes."

## A REDUCING SUBSTANCE IN HUMAN URINE RESEMBLING GLUCOSE.<sup>1</sup>

BY T. DARTON BRINE, M.D., OF BALTIMORE, MD.

AFTER completing the analysis already reported to this honorable body, I resumed the investigation of the urine on the 20th of last month, at the Johns Hopkins University Chemical Laboratory, and I take this opportunity of expressing my indebtedness to Professor Remsen for his kindness in offering me the facilities of the laboratory, and to Dr. C. Piggott, of the chemical department, for very efficient assistance courteously rendered.

As the behavior of this substance so closely resembled that of the compound reported by Dr. Walter Smith,<sup>2</sup> and believed by him to be proto-catechuic acid, the first step was to apply his method to the urine in question.

For that purpose, about 240 cc. of the urine were treated with an excess of a solution of neutral lead acetate and filtered. The filtrate gave the same brown and green reactions, with sodic hydrate and ferric chloride, respectively, that the urine did. It was then treated with an excess of a solution of basic lead acetate (Goulard's extract), and again filtered. This second filtrate did not respond to sodic hydrate and ferric chloride. The basic-lead acetate precipitate was then washed, suspended in water, and a stream of sulphuretted hydrogen passed through the mixture. The resulting black mixture was again filtered, and the clear, colorless filtrate responded to sodic hydrate and ferric chloride, as had the original urine.

This filtrate was then distilled in an atmosphere of carbon dioxide, and the distillate tested as before for the brown and green reactions, which were not obtained. The dark-brown, crystalline residue, however, dissolved in water, distinctly responded to sodic hydrate and ferric chloride, as had the urine, and, consequently, according to Dr. Smith, should have been proto-catechuic acid.

The quantity thus obtained was very small — too much so for an elementary analysis — so we determined to compare its solution with a dilute solution of pure proto-catechuic acid. On doing so, a marked difference was at once apparent. Our product in very dilute solution gave, with sodic hydrate, a faint reddish-brown color, rapidly becoming a deep brown on agitation in the air (that is, by oxidation), while proto-catechuic acid gave a very faint brownish color, only slightly deepened on agitation. With ferric chloride, our substance gave a distinct, but transient bluish-green, the liquid then becoming turbid, and of a dirty, greenish-white color. Upon the addition of sodic hydrate, the mixture becomes at first a bright bluish-green, then red, and on agitation, a brownish-red. Indeed, the readiness with which this substance took on a brown color in the presence of an alkaline solution (sodic and potassic hydrates and carbonates) was one of its most striking peculiarities. In the reaction with ferric chloride and sodic hydrate combined, the ferric chloride had to be added in very small quantity, lest on the addition of the sodic hydrate, ferric hydrate should be precipitated in quantity sufficient to obscure the result.

Proto-catechuic acid gave a bright, distinct, permanent bluish-green with ferric chloride, turned to a bright,

<sup>1</sup> Read before the Baltimore Academy of Medicine, January 18th, 1887. Continued from page 622, Vol. CXV.

<sup>2</sup> Dublin Journal of Medical Science, Vol. xxiii., p. 483, et. seq.

permanent, garnet-red upon the addition of sodic hydrate. With Fehling's solution, both gave a very similar reaction, namely, a slow and imperfect reduction of cuprous oxide, with a dark, greenish-brown discoloration of the supernatant fluid in the case of our substance, and a somewhat lighter color in the case of proto-catechuic acid. Clearly, therefore, our substance was not proto-catechuic acid, although very closely resembling it.

Just at this time, my attention having been called to Dr. Kirk's article in the *British Medical Journal* for November 27th, last, and the similarity of our substance to his "urhodinic acid" being so apparent, we determined to apply his method to the urine in question. Therefore, 750 cc. of the urine were evaporated down to about 60 cc., washed with several volumes of ether, separated from it and acidulated with hydrochloric acid (in the proportion of one-half per cent. anhydrous acid to the original amount of urine). The acidulated mixture was then shaken up with ether, and the yellow, ethereal extract separated from the urine. Both this extract and the ethereal washings gave the sodic hydrate and ferric chloride reactions, and on evaporation of the latter, and drying over sulphuric acid, we obtained large, needle-shaped, branching crystals (which I here show), mixed with resinous and coloring matters. Kirk's "serixanthine" we did not obtain. A small portion of the acid ethereal extract, evaporated spontaneously on a watch-glass, gave the beautiful crystals I exhibited at the last meeting of the Academy.

As we were not satisfied as to the purity of the crystals thus obtained, we subjected the bulk of this ethereal extract to Smith's method, and the resulting product was a reddish, crystalline body, which, on drying above sulphuric acid, gave off strong fumes of chlorine, showing that the hydrochloric acid had decomposed the original substance.

We determined, therefore, to purify by another method, and to use a very much larger quantity of urine. While awaiting this supply from the agent, I saw Dr. Marshall's publication in the *Philadelphia Medical News* for January 8th, 1887, and thus first became aware of his methods and results. As he has devised an apparently good method for the separation of this substance, and has isolated it in a purer state than we have as yet done, and intends to make a thorough investigation of it, we deem it in courtesy due to him to hold back any further publication, at least for the present, and give him the opportunity of completing his work, and of finding out exactly what this most interesting compound is. The crystals exhibited two weeks ago by me, and those which I now show under the microscope (obtained from the neutral lead-acetate filtrate prepared for the polarizer), are, I think, identical with those found by Drs. Marshall and Kirk. They are, as you have seen, needle-shaped prisms arranged in groups, radiating from a centre, like the spokes of a wheel. I believe, also, that this substance is identical with Smith's "proto-catechuic acid," Ebstein's and Müller's "pyrocatechol," and possibly, with Baedeker's "alkapton," although the latter was said to contain nitrogen, which Dr. Marshall says this substance does not.

At present my work stands thus: Quite independently of Dr. Marshall, and in ignorance of his methods and results, I have the honor of reporting to this Academy a crystalline-reducing substance found in

human urine, capable of being confounded with glucose, very similar to proto-catechuic acid, and apparently identical with Kirk's "urhodinic acid." That this compound results, as Kirk suggests, from "a profound perversion or arrest of the metabolic processes" is possible, and, inasmuch as the applicant had eaten nothing known to give rise to a reducing substance, perhaps probable; but in this, as in the majority of other similar cases, there was no apparent disease, and we are, consequently, compelled at present to state that *this substance has no known pathological signification*. Of course, a knowledge of its ultimate constitution may throw further light on this subject.

In conclusion, without occupying your time with an account of the origin and reactions of other reducing agents (principally derived from ingesta), a number of which have been found in human urine, *I will simply emphasize the fact that their occurrence, as well as the discovery of this new compound (if new compound it be) render it necessary to employ other tests to corroborate the positive evidence of Moore's and Fehling's tests for glucose in human urine.*

## REPORT ON PROGRESS IN GYNECOLOGY.

BY F. H. DAVENPORT, M.D.,  
Assistant in Gynecology, Harv. Med. School.

### THE INITIAL STAGES OF FIBROIDS.

OLSHAUSEN,<sup>1</sup> in a paper read before the first meeting of the German Gynecological Society, held in Munich, gives what he considers to be the initial stages, clinically, of fibroids. The evidences of the beginning of a fibroid which appear before the tumor can be at all recognized, consist in a series of subjective symptoms, especially pains which grow worse during menstruation, but do not cease in the intervals, a feeling of great pressure, irregularities in the menstrual flow, in which it comes too early, and lasts too long. There are abnormal sensations of the bladder as well. The uterus is found to be sensitive to pressure, especially on bimanual examination. These symptoms last a varying length of time from a few months to several years.

After a time the uterus is found to be enlarged, and again after a lapse of time the presence of a fibroid is recognized by its irregular form. From this time the pains cease, and the menstrual flow diminishes in amount, or ceases altogether.

This chain of circumstances can be explained in two ways: either the very earliest stages of the growth of a fibroid give rise to symptoms which disappear with its increased size, or the irritation of the uterus is the primary cause which leads to the development of the tumor. Olshausen considers the second explanation the more probable. Women in whom these prodromal symptoms have lasted for years, are usually sterile during that time, and this symptom is a consequence of a congested state of the uterus which sooner or later leads either to the development of a fibroid or to areolar hyperplasia. In conclusion, Olshausen expressly states that he does not mean to say that this explains the development of fibroids in all cases, but that in numerous cases he has observed this sequence of events.

In the discussion Winckel said it was his opinion

<sup>1</sup> Wiener Med. Presse, No. 31, 1886.

that when such initial symptoms appeared, already small fibroids existed which could not be demonstrated, and that the pain was caused by the stretching of the walls of the uterus by these small growths. The difficulties cease when they have grown out of the wall of the uterus.

PREPONDERANCE OF MALES FOLLOWING CONCEPTION AT THE TIME OF THE POST-MENSTRUAL ANÆMIA.

The solution of the question when and why the determination to the male or female sex takes place has always excited interest. These inquiries have not yet found satisfactory answers, partly because they have rested on a purely theoretical basis, and partly because in the investigation of one factor, the influence of others has not been considered. Therefore even a small contribution to the settlement of the question is welcome, which excites to further investigation, and seems a step in advance.

C. Fürst<sup>2</sup> opens his article with a short sketch of the generally prevailing opinions as to the time and causes of the determination of sex. In accordance with these it is probable, or at any rate not disproved, that the determination can take place as well before, as during, and even a certain time after the impregnation. As regards the cause, there must be supposed a coöperation of different causes at different times. Among the causes affecting both parties, the influence of better or poorer nutrition has been proved by numerous examples (relatively more males when the nutrition is poorer). If one supposes that such an influence can also be exerted through the nutrition of the already impregnated ovum, then it must, in accord with the very early predisposition to the formation of the genital organs, be the greatest soon after conception.

Fürst came upon the idea, that in cases of conception immediately after the cessation of the menstrual flow there would on account of the poorer nutrition of the impregnated ovum be a preponderance of boys. With this in view he selected from the large material of the Vienna clinic of C. Braun, those cases in which the day of conception was known, and separated the cases of which he was sure, (one hundred and thirty-three), from the less trustworthy (sixty). A study of these cases gave the rather noticeable result of a marked preponderance of boys for the cases in which conception occurred within the first four or five days after the cessation of the menses, thirty-seven boys to twelve girls, and a preponderance of girls for the rest of the interval, seventy-nine girls to sixty-five boys. In sixty-seven cases where the accuracy of the data admitted of no question, the proportion was still more marked, fourteen boys to two girls, and twenty-nine girls to twenty-two boys.

Even if this number of cases is too limited to enable us to lay down the rule that conception at the time of the post-menstrual anæmia is followed by a large preponderance of boys, it can at least lead to farther investigation.

A CONTRIBUTION TO THE DETERMINATION OF SEX DERIVED FROM OBSERVATIONS MADE ON AN AFRICAN TRIBE.

Dr. R. W. Felkin<sup>3</sup> gives the results of some observations made on the Waganda tribe, which are interesting for their bearing on the question of the deter-

mination of sex. The female population in Uganda is largely in excess of the male, the proportion being about three and a half to one. This preponderance is due to three causes, first, more female births than male; second, as the Waganda are constantly at war, and their battles are very destructive, the death-rate among the males is greater than among the females; third, the custom after a victory of putting to death the men, but sparing the women and children.

With regard to the first point, the writer made inquiries into the history of three hundred pure Waganda women, and found that two hundred and ninety-one had children, and of the first births, one hundred and forty-four were males, and one hundred and forty-seven were females. Of five hundred imported women, four hundred and eighty-two had children, and of the first births only seventy-nine were males, and no less than four hundred and three were females.

The theory which Felkin advances to explain these facts is that "the temporarily superior parent produces the opposite sex." The fact that the imported women at their first births are liable to produce females is accounted for in this way: When in the course of the wars a town is captured, the soldiers are allowed the utmost license, and the nights are spent in excess of every kind. The men, flushed with victory, and exhilarated with wine, are temporarily superior to the women, frightened and sorrowful at loss of home and friends and freedom, and exhausted by long marches. Later, after the captives have been distributed as views and have settled in their new homes, the proportion is more nearly that of the pure Waganda woman, namely, one hundred males to one hundred and thirty-seven females.

Incidentally, Felkin noticed the very small proportion of sterile women, both among the pure Waganda, and among the imported women. The former showed only three per cent. and the latter three and six-tenths per cent., as against about fifteen per cent in England.

RELATION BETWEEN NEUROSES OF THE STOMACH AND UTERINE AFFECTIONS.

Dr. Gustav Braun<sup>4</sup> refers at the beginning of this article to the frequency with which certain organs when diseased exercise a very marked influence on other organs remotely situated, while with regard to others, for example, the lungs, no such observations are made. The stomach and female genital organs belong to the first category.

We know that changes in form and position of the uterus may cause gastric disturbances, and there are other uterine affections which may have similar effects. Dr. Braun gives the histories of three interesting cases which illustrate this connection.

CASE I. A woman, twenty-five years old, married at seventeen, had a child one year later. Several years after she had an attack of angina tonsillaris, from which time there appeared disturbances of digestion, beginning with loss of appetite, and ending with constant vomiting. Various forms of treatment, including a sojourn at Carlsbad, relieved her only temporarily. Finally, an examination of the condition of the genital organs by Dr. Braun showed a normal condition of affairs except excessive mobility of the uterus. It could be easily pushed by the examining finger into a position of ante or retro-version or even latero-version. On the supposition that this might be a factor

<sup>2</sup> Archiv. für Gynäkologie, xxviii-1.

<sup>3</sup> Ed. Med. Journal, September, 1886.

<sup>4</sup> Wien. Med. Woch. 1886, Nos. 41 and 42.

in the case he fitted a Hodge-Braun pessary, from which time the vomiting ceased, and the patient fully recovered her health.

CASE II. This patient, thirty years old, married, had one child two years old. The birth was normal, but the child large, and the head very hard. Gastric disturbances showed themselves very soon, followed by vomiting, at first only when she was on her feet for a length of time, but later when sitting or lying. After a good deal of unavailing treatment, a vaginal examination revealed a deeply lacerated cervix, with a cicatrix in the right angle of the laceration. Pressure with the examining finger provoked retching and vomiting. The operation for the repair of the cervix was followed by immediate and lasting relief.

This patient, twenty-eight years old, had given birth to a child two years before. Soon after she experienced a feeling of weight in the pelvis, but paid no special heed to it until some months later, when on lifting her child she felt sudden pain in the lower abdomen. From that time vomiting followed as often and as long as she was on her feet, but when lying down she was comfortable. Pessaries were of no use, as the small sizes did not prevent the sinking of the uterus, and the larger ones caused too much pain. Examination showed a large uterus over five inches in length with the cervix very much hypertrophied, which pressed against the intact perineum when she stood up. Rest in bed, and hot-water injections failed to reduce the size of the uterus, therefore the amputation of the vaginal portion was performed, with the result of reducing the size of the womb to a little over three inches, and a complete cessation of all troublesome symptoms.

#### POLYMASTIA WITH TEN NIPPLES.

DR. F. S. NEUGERAUER, Jun.,<sup>2</sup> reported the following case before the meeting of German Naturalists and Physicians held in Berlin in September, 1886.

X. X., twenty-three years, was confined for the second time at the Lying-in Hospital in Warsaw. She had nursed her first child born seven years before, and noticed nothing peculiar about the breasts except some brown spots on the chest which she regarded as mother-marks. After the second confinement she noticed even on the second day, a disagreeable moisture and dripping under the arms. Examination showed two nipples without areolae in the axillae, and in addition two more on each side above and to the outside of the normal ones. When the breasts were raised two additional ones were discovered underneath them, making ten in all. When the child nursed, milk trickled spontaneously out of the axillary nipples, but could only be pressed out of the other six.

The author asks the question, whether we have to deal with several nipples on a single gland, or with several distinct mammary glands, each with its own nipple, and inclined to the latter view. He then gives the various theories which have been held as to the cause of these accessory breasts. Ahlfeld explains them by supposing that by the pressure of the amnion, portions of the formative layer are cut off and adhering to the amnion are transplanted to the surface of the body.

Others explain their existence as the result of the aberration of milk ducts. Lichtenstern and many others regard this anomaly as a manifestation of

atavismus. The author favors the latter view. Champney is referred to, who has written a paper advancing the theory that in certain puerperal women the sebaceous glands become changed into, and take on the function of mammary glands.

#### MOLLITIES UTERI.

Under this name Dr. Scudder<sup>3</sup> describes an extraordinary softness which sometimes affects the uterus. Dividing the organ into three segments, the cervix, the middle segment, by which he means "the supravaginal cervix with that portion of the uterus containing the internal os;" and the body or upper third, he finds that this abnormal softening may affect one portion alone, or the organ as a whole.

The softening incident to pregnancy, especially of the cervix, is familiar to all. This, according to Scudder, may successively invade the middle segment and the body, though much less frequently than the body alone. This same condition may be found in women who are not pregnant, both nulliparæ and multiparæ. The diagnosis is easily made in the case of the middle segment, by the mobility of the body without affecting the axis of the cervix, in the case of the body, by the ease with which it is molded. The author has found mollities of the middle segment most common in nulliparous women. He considers it due to "malnutrition of the body as such, and of the uterus in particular, such malnutrition of the uterus being aided by congestions or inflammations of the uterus, ovaries, or surrounded tissues and organs, or by pregnancy, neoplasms, etc."

When the middle segment is affected, the symptoms are at first general in character, with some indefinite pelvic distress. Later come menstrual disorders, dysmenorrhæa, menorrhagia and sometimes metrorrhagia and later trouble with micturition, and ovarian dysmenorrhæa. Antelexion or retroflexion followed, the direction seeming to be determined by the position of the uterine axis.

Treatment is constitutional and local. Good hygienic surroundings, tonics, and regulation of the bowels, are essential as general measures. Local treatment would include the reduction of the misplacement, and the adjustment of pessaries and uterine massage.

#### ON SOME OF THE PHYSIOLOGICAL AND THERAPEUTICAL EFFECTS OF WATER AT DIFFERENT TEMPERATURES WITH SPECIAL REFERENCE TO OBSTETRICAL AND GYNECOLOGICAL PRACTICE.

MR. R. MILNE MURRAY<sup>4</sup> has written a very interesting article on this subject which places on a scientific basis the use of hot and cold water in the treatment of inflammations and hemorrhages.

For a very long time cold applications have been used in the checking of hemorrhages from the uterus, and in recent years water at relatively high temperatures has been recommended as being more efficacious. The evidence thus far has been based almost entirely on clinical experience, and the effect is supposed to be a two-fold one, by causing a rigid tonus of the uterus, and more or less persistent spasm of the muscular tissue of the bloodvessels.

Emmet, whose name is prominently associated with the advocacy of the use of hot water, says the imme-

<sup>2</sup> Centralblatt für Gynäkologie, 1886, No. 45.

<sup>3</sup> New York Medical Journal, December 18th, 1886.

<sup>4</sup> Ed. Med. Journal, Aug. and Sept., 1886.

diate effect is to cause relaxation of the bloodvessels, but if the application be prolonged, reaction ensues, and contraction takes place. To determine the truth of this theory, the author conducted a series of experiments with hot, warm and cold water on the muscular tissue of the uterus, as well as non-striated muscle generally.

The method of experiment, and the various tables giving the results, are interestingly set forth in the article to which the reader is referred for details. The following table will show the more important facts settled by the investigations.

## GENERAL VIEW OF THE ACTION OF COLD AND HOT WATER.

COLD, 32° to 60°.	HOT, 100° to 120°.
(1) Marked latent period.	(1) Latent period absent or very short.
(2) Contraction develops slowly.	(2) Contraction develops rapidly.
(3) Relaxation about three times duration of contraction.	(3) Relaxation about twelve to twenty, four times duration of contraction.
(4) Successive applications can only induce contraction after period of rest. These contractions become greatly diminished in efficiency, the period of relaxation and maximal contraction being greatly reduced. Loss in four experiments four-fifths of initial efficiency.	(4) Successive application followed at once by response. Efficiency of contraction greatly increased. The period of relaxation, and maximal contraction are much increased. Gain in four experiments four times initial efficiency.
(5) Continuous application produces rapid exhaustion, muscle becoming completely relaxed and failing to respond.	(5) Continuous application induces a high degree of contraction, broken up by secondary waves of partial relaxation and contraction.

The following deductions are drawn from the experiments:

1. Water at temperatures of 120° F., and ten degrees lower constricts bloodvessels, and arrests hemorrhage from small arteries.

2. Water at temperatures of 100° F., and thirty or forty degrees under dilates small vessels, and promotes hemorrhage.

3. Water at temperatures of 50° F., and twenty degrees under, checks hemorrhage by constricting bloodvessels, but this only temporarily.

4. After water at the above temperatures has lost its styptic power, water at high temperatures is still effective.

The therapeutic significance of the experiments may be epitomized as follows:

I. It is evident that in water at 120° F., we have an agent of immense power in controlling the local circulation in an organ. The calibre of the smaller bloodvessels becoming narrowed, the abnormal blood-supply will to a large extent be cut off, and the resulting phenomena of inflammation checked.

II. Hot water is efficacious in promoting uterine action, and is hence useful both in cases in which the contents of the uterus have not yet been expelled, and those in which they have, but where the risk of hemorrhage is imminent from atony of the uterus. In post-partum hemorrhage it is especially indicated on the following grounds: (1) The rapidity of action; (2) The duration of the tonus produced; (3) The absence of vascular reaction; (4) The absence of exhaustion of the muscular fibre; and (5) Absence of violent shock to the exhausted system.

— It is reported that Dujardin-Beaumetz is using antifebrine extensively in the treatment of epilepsy, and that he considers it one of the most powerful moderators of the spinal centres.

## Therapeutical Memorandum.

## THE TREATMENT OF SCIATICA. A SUCCESSFUL TREATMENT OF ACNE.

BY JOHN T. METCALFE, M.D., NEW YORK.

For many years past I have been in the habit of prescribing a method of treatment for this so often unyielding neuralgia of the sciatica, which is so simple and at the same time has so satisfactorily answered my purpose that I should be glad to have some of the many readers of the JOURNAL give the benefit of their clinical experience in determining the true value of what was accidentally made known to me in the way of a remedy for the "obprobrious" ailment in question.

I need not premise that my remarks are only applicable to that form of sciatica in which we either refer the cause to some diathetic influence, especially the gouty or rheumatic, or to those more obscure in their nature to which we are unable to give a name. Cases due to growth in the nerve or to pressure on its trunk or roots must be relegated to the surgeon's consideration when not of syphilitic origin. In that event any one would naturally be led to adopt specific medication, alone or in conjunction with the treatment of which I wish to make especial mention.

Nearly thirty years ago a prominent New York shipping merchant, with well-marked gouty diathesis, applied to me for relief from left sciatica. He was nearly sixty years old and had led a remarkably prudent and temperate life, his only resort to his medical adviser had been for gout and rheumatism, as his somewhat frequent attacks, for the ten or fifteen previous years had been called.

The suffering was unusually great and notwithstanding rare power of enduring pain soon became unbearable. I will not detail how I had excluded all possible cause of surgical nature; nor how I had used almost every known means to relieve the pain and to procure sleep by internal administration of so-called remedies for his constitutional ailment. I knew that opium was unfriendly to him, but after failure of everything else, I used the sulphate of morphia in doses of one-sixth of a grain subcutaneously. Much relief and more sleep were the immediate results of the anodyne; but the papaverous poisoning and prostration were so alarming that I could not bring myself to repeat the medicine. After a week or ten days, the intense pain subsided, mainly as was then thought, from the constant application of rubber bags and bladders, filled with water as hot as the patient could bear it. Blisters and the actual canterly had not given the slightest relief, except on one occasion, when sprinkling the denuded true skin with one-third of a grain of acetate of morphia acted as unfortunately as the subcutaneous use of the sulphate had done.

As the winter was severe, I advised my patient to pass two months on the island of Cuba, giving him all manner of diathetic and regimenal directions; and strongly advising him to eschew all "doctor's stuff." At the end of the time mentioned, he returned, perfectly well of his torturing ailment. As was natural I complacently and *vis* voce congratulated myself on my clever prescription. "Not so fast," said he, "my dear doctor, I almost died with the infernal thing after reaching my friend's plantation. He sent for an old

French doctor who attended his negroes and family and from him I received a bottle of medicine, which without containing opium in any form, gave me very speedy relief. I know it was not a mere coincidence; for I have tried it twice, since he prescribed it, with exactly the same result. Here is the prescription. It was composed of equal parts of tincture of aconite root, seeds of colchicum and belladonna.\* The dose was six drops, every six hours, until relief came.

During my old friend's life, his new remedy never failed to give him relief. For many years I continued to prescribe it in sciatica of the kind named; and although I have had some unsuccessful cases, I have come to believe that, as an internal remedy it is worth all others put together of which I have knowledge.

Some months ago I got Mr. Fraser to make tablet-triturates, each of which contain three drops of the following mixture;

Tincture of Aconite Root	} Equal parts by volume.
" Seeds of Colchicum	
" Belladonna	
" Actea Racemosa	

Of these, I give one, every four, six or eight hours, according to the necessity of the case. It takes not long to impress the system, especially with the aconite, nor does it as a rule require more than three days to make the patient so firmly believe in its efficacy that he has no need of persuasion to ensure its continuance until complete relief.

To many physicians I have given the formula just mentioned. In neuralgia of the axillary and brachial nerves, it has proved quite as efficacious as in that of the great crural branch. As yet, I have not seen one brother Esculap who has not thanked me for having led him to try the remedy.

#### A SUCCESSFUL TREATMENT OF ACNE.

Judging from my own experience, I do not think the case with which acne, whether of the sebaceous, pustular or papulous form is curable, by external means, is generally very gratifying to patient and practitioner. For the last seven years I have not failed in a single instance to perfectly cure the ten or twelve cases which have come under my observation.

Some have been of long standing and of great severity. The last very bad one was facial and so disfigured the doctor to whom the face belonged that he only went into society with the greatest reluctance. When I told him that I felt sure he could be greatly benefited and that I thought he could be cured, he said he had given up all hope of amendment and had made up his mind to practice philosophy in accepting the inevitable.

I met my confrère a week ago and actually failed to recognize him at first, so entirely was his face free from the disfiguring acne.

I was led to employ chrysophanic acid in these cases, by reason of learning what it had effected when used as an ointment in treating chronic psoriasis. My habit is to begin with an ointment made of three grains of the acid to an ounce of vaseline. The face is well washed with soap and dried, at night. Before going to bed, the parts in which acne exists are well rubbed with the ointment and this is repeated, every night, until a sharp dermatitis with scarlet skin is produced. Inunction then ceases, until disappearance of the artificial inflammation of the skin, when a repetition of the ointment is made, under conditions above stated.

In all delicate skins, the three grains strength is sufficient. In others it may be necessary to increase the percentage of chrysophanic acid until sufficient dermatitic power is produced. Almost never have I been obliged to go beyond five grains to the ounce. It is necessary to caution patients that the bed-clothes and garments be not stained by the ointment, and to have them wash the fingers well that the eyes may not be made to suffer.

## Reports of Societies.

### PROCEEDINGS OF THE OBSTETRICAL SOCIETY OF BOSTON.

C. M. GREEN, M.D., SECRETARY.

#### TWENTY-SIXTH ANNUAL MEETING.

JANUARY 8, 1887, the President, DR. A. D. SINCLAIR, in the chair.

DR. WM. L. RICHARDSON read a paper on

#### THE USE OF ANTISEPTICS IN OBSTETRIC PRACTICE.<sup>1</sup>

DR. CURTIS said he had previously heard Professor Richardson's lectures on this subject and had been very much interested in his personal observations of antiseptic obstetrics at the Boston Lying-in Hospital. The contrast between the clinical charts of this hospital in former years and those of the present time was very striking. A by no means unimportant fact coincident with the introduction of the present antiseptic treatment was the absence of ophthalmia neonatorum. He believed that the same system of rigid antisepticism should be introduced into private practice.

DR. BLAKE said that in hospitals the septic influences were such that strict antiseptic precautions were necessary, and the system adopted by the reader was admirable; but he was not prepared to believe that the same precautions were essential in private practice. Many physicians of large experience in the past had lost no cases from puerperal fever and had never taken especial antiseptic precautions. The conditions and surroundings of patients are the same now as then, whence, therefore, the necessity of especial precautions now? Of course, if the surroundings or the condition of the patient were such as to make the physician apprehensive of danger, or if the physician himself had been exposed to septic influences, it would be his duty to use appropriate precautionary measures; but he was yet to be convinced that such measures were necessary in ordinary cases.

DR. LYMAN thought Dr. Blake's objections to strict antiseptic in private practice were not tenable. Deaths from puerperal fever do occur in private practice as well as in hospitals. The vast majority of general practitioners have but a limited experience in comparison with those connected with public charities, and if the ratio of mortality between this public and private practice could be honestly worked out, the immunity claimed by the latter would, perhaps, not be so much a matter for congratulation. He had himself, with a comparatively limited experience, lost three cases from this cause in years past and he would not now feel at ease in conducting obstetric cases without rigid antiseptic precautions. If there be doubt as to their necessity, it is unquestionably our duty to give the

<sup>1</sup> See page 73 of this number of the Journal.

patient the benefit of the doubt. He thought that no man had a right in the present state of our knowledge to ignore these precautions. He hoped the reader's paper would have a wide-reaching influence for good.

DR. DOX said that the chart portraying the hospital's experience corresponded very closely with his own results in practice. Until six years ago he had taken no especial precautions and had used the ordinary napkin as a covering to the vulva: during that period of his practice he had four cases of puerperal fever. After that he began to use a compress or pad of carbolized cheese cloth and borated cotton; thereafter he had no septicæmia, but did sometimes have cases that caused him anxiety from rise of temperature and abdominal tenderness. Since the autumn of 1885 he had used a pad of cheese cloth and tissue rubber dipped in a 1 in 1000 solution of corrosive sublimate, and had used the same solution for disinfecting his hands. It was his custom also to have the genitals bathed every three hours with a 1 in 2000 solution, and a vaginal injection of the same strength was administered just before the birth of the child. Since adopting this method he had had no anxious cases. The fact that some practitioners of large experience had had no puerperal fever in the past was not a reason for omitting antiseptic precautions in the present day. Nor are these precautions necessary only in hospitals; for the danger of infection by the finger of physician or nurse is as great in private practice as in hospitals, and particularly so with physicians in large practice who are seeing continually both contagious and non-contagious cases.

DR. CHADWICK said that he had restricted his obstetric practice to such a degree that his recent experience did not enable him to contribute much to the present discussion. He could recall four or five cases of puerperal septicæmia, which at the time of their occurrence he was inclined to think were auto-genetic; but in the light of recent scientific work he was now satisfied that the infection was communicated by himself or others, although so far as he knew at the time he had been exposed to no special septic influences. He was in hearty accord with the teachings of the paper, and thought the methods recommended by the reader should be adopted in private practice.

DR. ELLIOT said the conditions of infection were the same in surgery as in obstetrics, and the proposed obstetric pad was like a Lister dressing; other things would do as well or better in either case. Winckel arrived at the conclusion before 1879 that the germs, which infected a patient, came not from the air (although the air is theoretically full of micro-organisms) but from the examining finger of nurse or doctor and from instruments; he believed, in short, in contact-infection and not in air-infection. Winckel did not, therefore, believe it was dangerous for a healthy puerpera to occupy a bed next to an infected patient, provided nothing from the infected patient came in contact with the healthy one. Great pains were therefore taken in Winckel's wards that fingers and instruments should be aseptic and no pads were used; and his mortality was only one-half of one per cent. It was hard for Dr. Elliot to believe in air-infection, when he knew that the peritonæum could be exposed during operations without spray for an hour or more without infection. He thought that Dr. Richardson's good results during the past year were not due to the introduction of the antiseptic pad, but to a most care-

ful and laborious drill of assistants and attendants in the details of cleanliness. Dr. Elliot had used corrosive sublimate in ovariectomy for cleansing hands, sponges, etc., for several years, and had found it to be on the whole the best antiseptic.

DR. BOARDMAN remarked that he had little if any thing to say except to commend the paper and to confirm the deductions made therein. While, of course, he had had an intimate relation with what had been tried and accomplished at the hospital and had contributed his share to the ill results and claimed a participation in the benefits attained; while he had observed, in a general way, the gradual improvement in the condition of the patients, which had been exhibited under the successive methods of treatment that had been followed since his connection with the hospital, he by no means had appreciated to its full extent, until very lately, the gradual evolution of the central idea which is embodied in the paper and which is so graphically illustrated by the diagrams, and he desired too, to take this opportunity to disclaim any credit for participation in the preparation of the paper which, obviously with much labor and care, had been written by his colleague alone, although with the utmost courtesy throughout he had kindly employed the plural "we" when the first person singular would have been more appropriate in most instances.

He thought it proper, too, to state that daily vaginal douches were finally abandoned only after mature consideration, and the responsibility for this change was assumed by Dr. Richardson, he (Dr. Boardman) having declined to initiate the change because he felt that under their use a notable improvement in the condition of the patients had been observed; indeed, he thought, at the time, that the results obtained were, perhaps, the best possible in a hospital and he felt that it was best to let well enough alone. The results of the experiment, however, appear to confirm the wisdom of the change as is very well illustrated in the diagram marked "dangerous," which, upon the very liberal though arbitrary standard adopted by the writer, indicates a notable improvement during the year 1886, when the douches were abandoned. And, again, this same diagram, taken in connection with the statements of the successive methods of practice which have obtained at the hospital, shows, at a glance, remarkably well the development of the fundamental rule which, we believe, should govern in obstetric antiseptics, namely, that success is to be reached by rendering the patient aseptic at the start, so far as we can, by preventing the admission of the germs which, it is believed, most if not all physicians of the present day regard as the efficient agents in producing sepsis, and which we believe must come from the outside, thus differing essentially in no wise from the methods most generally followed at the present day in abdominal and general surgery.

The lesson inculcated by the experience of Winckel, to which reference has been made by a previous speaker, and which by no means was peculiar to or original with him, was a valuable one, as every one must admit, and, in my opinion, may be employed as a valid argument in support of the theory which the paper is intended to advocate, namely, the prevention of the introduction of septic germs within the utero-vaginal tract. If recollection is not at fault, in Winckel's subsequent service septic cases have occurred which could not be traced to similar causes. In the

Boston Lying-in Hospital, too, before it was the custom to employ vaginal douches daily, when patients were treated in the traditional, let-alone way, except that external cleanliness was maintained, septic cases have repeatedly occurred which could not possibly be explained by the immediate contact of those who had charge, and made vaginal examinations, of the patients, at least so far as could be determined at the time. While we must admit the possibility of such an occurrence, it is believed that the paper demonstrates the fact that other factors have operated, as a general rule, to produce these many septic cases.

Individuals commonly refer to a large personal obstetric experience where no antiseptic precautions have been taken and yet they record a very small mortality and a trifling percentage of, or no, septicæmia, even when, as a rule, the surroundings of their patients would seem to have been such as to have favored the occurrence of this affection in many instances. They argue from these premises that the general practitioner is not called upon to resort to the precautionary measures under discussion which, however, they generally admit may be demanded in hospitals. In this connection we must not lose sight of the fact that the experiences of many, if not most, of these individuals extend back into years when the term puerperal fever included a multitude of ills, so to speak, when septicæmia was not at all, or imperfectly understood, and, too, a general statement of experience, covering many years and not confirmed by a definite reference to recorded details, is always open to question as to its accuracy. Admitting, however, the notable freedom from septicæmia in the practice of some individuals, the fact remains that septic cases do occur outside the hospitals, as is proved by the life insurance statistics to which allusion has been made in the paper, wherein it is stated that among 2,000 females insured quite a large proportion died from puerperal affections and accidents, and among the deaths a very large per cent. occurred from septic causes. These cases, in all probability, occurred in private practice and, further, it may rightly be assumed, in well-to-do classes of society and this fact alone would seem to invalidate the argument drawn from the favorable reports of individual experience.

It is understood from the paper that the records of the hospital indicate a pretty gradual disappearance of septicæmia in quite direct conjunction with the approach to the present practice of avoiding the disease by the most strict adherence to rigid rules which are regarded as efficient in preventing the entrance of bacteria into the parturient canal. It appears, too, that the paper shows quite conclusively that the disappearance of the disease from the hospital has not simply followed a law which has seemed obvious in some periods and assumed in others, that the septicæmic influence "has come and gone," without reference to treatment which has been employed against it, and this inference is confirmed by the similar and nearly simultaneous experience elsewhere, in this country and abroad, in localities so widely separated that it would be utterly unreasonable to refer to this so-called cyclic law or law of self-limitation as a valid argument against the deductions which the reader has made.

Dr. STRONG said that the introduction of antiseptics into obstetrical practice, as described by the paper of the evening with its convincing array of statistics, was a notable event in that department of medicine, being

the first complete experiment of that kind in New England. It seemed to him that any practitioner neglecting to enforce the principles laid down here must feel a direct personal responsibility for septicæmia among his patients. In regard to the slight danger of infection from bacteria of the air, as was shown by the immunity during long operations on the peritoneum, the cases seemed to the speaker not parallel, as in the one every precaution is taken in the way of ventilation, painting walls and floors, and insuring as thorough disinfection as possible; in the other, the air that comes in contact with the exposed surfaces is that confined under the bed-clothes of the lying-in woman, a most fruitful source of germs for infecting the lochial discharge.

The speaker thought it a great gain to have a safe and agreeable substitute for the vaginal douche in private practice; being convinced of the dangers that possibly attended the douche, it had been his custom never to employ it as a routine treatment, reserving it for personal administration only. As the speaker passed through two severe epidemics at the Lying-in Hospital, while house-pupil several years ago, he realized better than most of those present what the statistics meant in the way of freedom from anxiety and hard work.

He inquired what advantage was to be gained from the "sprinkler" rather than bathing the vulva, and if the pads were stained through. He was answered that patients liked sprinkling better, and the nurse was not obliged to touch the vulva: the pads were changed with sufficient frequency to prevent their being stained through.

In concluding, the speaker said that in obstetrics as in surgery, absolute cleanliness was the desideratum; in certain cases this could be accomplished by the use of pure air and water; but in the majority of cases more was needed, and this was the advantage which thorough and systematic employment of antiseptics gave; it ensured cleanliness, it was the easiest method of keeping the parts aseptic.

Dr. REYNOLDS admitted the pertinence and the importance of the criticisms made by Dr. Elliot; but he was not prepared to adopt unhesitatingly the conclusions to which those remarks pointed. Some of the speakers scouted the idea that grave and fatal disease occurs in any appreciable proportion, out of hospitals. The monthly mortality returns furnish constant evidences that this statement is not well-founded. Dr. Reynolds recalled in the first twelve years of his professional life, four cases of death among lying-in women, his patients being largely of the poorer class; one at least of these, an attack of the foudroyant type, where the fatal result occurred on the second or third day, after an illness of thirty-six hours, though he knew no explanation of it in the facts of the birth. Within only the last fortnight, he has seen in consultation two cases of septic poisoning that ended fatally in the second week of the lying-in. Both these women were in comfortable quarters; each of them has been attended by a man of the best ability, well known in this community. In neither case had the antiseptic pad been employed; although ordinary precautions against infection had not been neglected.

Dr. Reynolds is as unwilling as any colleagues can be to advocate fussy precautions in the lying-in room, or even in our attempts to control other forms of infectious disease. It is not unlikely that after a time,

perhaps after a comparatively short time, many details of the treatment which Dr. Richardson has described may be found unessential. This is, however, not yet true and our present obligation may be thus stated. After all child-birth a certain percentage of danger from septic poisoning exists. In lying-in hospitals, where all the causes of risk are greatly increased, the immunity from every disturbance of health, which the use of the aseptic pad secures, is simply marvellous. This contrivance is not costly, is easily applied, and gives great comfort. He who, in our present state of knowledge, rejects it in his private practice, becomes directly responsible for any dangerous septic symptoms that his patients suffer.

DR. BAKER said his experience at the Free Hospital for Women, before and after the adoption of rigid antiseptics, coincided with the results at the Lying-in Hospital. Although after labor there is a more extensive surface from which septic germs may be readily admitted, still in purely gynæcological practice there is sufficient opportunity for septic infection in the absence of efficient precautions. The Free Hospital has always been closed in summer and thoroughly fumigated with sulphur. Still, before the days of antiseptics, it was only in the fall and early winter that temperatures were low after operations: by February, temperatures began to run high and frequently operative work had to be suspended; thus much time was lost. When carbolic acid came to be generally used, there was some improvement in the general course of the cases. But since the spray had been given up, and corrosive sublimate had been used to bathe the parts during operations and to sterilize all germs on the hands of surgeons, assistants and nurses, temperatures had been low, cases had run smoothly, and there had been no occasion to suspend the operative work of the hospital. This experience proved to his mind the convincing character of the paper, and he thought the reader was entitled to great credit for the able manner in which he had brought the subject before the Society.

DR. GREEN said that the advantages of rigid antiseptics accrued not to the patient alone, who indeed was first to be considered, but to the physician as well, inasmuch as the chief anxiety of obstetric practice was thereby dispelled. Since he had adopted the methods now so clearly laid before the Society, he no longer apprehended the invasion of septicæmia in his cases, and his main care was the process of lactation and affections of the breasts and nipples. It seemed to him, therefore, that a purely selfish desire to be relieved of anxiety was a sufficient inducement for the physician to conduct his cases antiseptically.

The students of the Harvard Medical School who were put in charge of obstetric cases were instructed to conduct their cases with every attention to antiseptic detail. During the year 1886, over three hundred women, out-patients of the Boston Lying-in Hospital and Boston Dispensary, had been attended by students under his supervision: in this number occurred only two cases of septicæmia. One of these two cases was delivered by a midwife before the student arrived, and the other was conducted without antiseptics: both cases, however, recovered. Not only this, but there was a marked absence of high temperatures and abdominal tenderness, which features had been a frequent cause of anxiety before the method now in vogue had been adopted.

In closing the discussion Dr. RICHARDSON said that he was glad the sentiment of the meeting had been so favorable to the use of antiseptics in obstetric practice. While he agreed with Dr. Blake that septic cases were comparatively rare in private practice, he thought that their rarity had been overestimated, and that it should be our aim to avoid all danger, even though the possibility of the danger occurring was but slight. He had used in the hospital the corrosive sublimate in the strength of 1 to 2,000: but, having seen a few cases of mercurial poisoning follow the use of a solution of that strength, the proportion had been changed to 1 to 3,000, which was the strength now used by Professor Winckel in Munich. The use of the pad was merely to provide some safe antiseptic substitute for the napkin formerly used; and no especial merit was claimed for this particular form of pad.

## THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting, December 16, 1886.

DR. HERMAN KNAPP delivered an address on

FERMENTATION, PUTREFACTION, AND SUPPURATION, WITH DEMONSTRATIONS AND EXPERIMENTS.

In introducing the subject, he spoke of the immense importance of bacteriology, which he thought was not yet sufficiently appreciated in this country. He had been particularly impressed with a remark made by Professor Brieger, of Berlin, a short time since, to the effect that the great majority of all diseases seem, in the light of recent investigation, to be of bacterial origin. In support of the correctness of this proposition, he referred to the weekly mortality lists of different cities, as reported in the *Boston Medical and Surgical Journal*. During the week ending August 28, 1886, the number of deaths from infectious diseases in New York City was set down at thirty-three per cent. of the total mortality; those from consumption at sixteen per cent.; and those from croup and diphtheria at about five per cent. Here were nearly fifty-five per cent. of all deaths attributable to diseases of undoubtedly bacterial origin. In addition, twenty per cent. of the deaths were from diarrhoeal diseases, and at least ninety per cent., if not all of these, were cases of germ disease. This brought the percentage up, therefore, to seventy-five; but this did not include such affections as pneumonia, peritonitis, syphilis, gonorrhœa, and skin diseases; and if only ten per cent. of these were classed as of this character, it would increase the percentage to eighty-five. As yet, however, nothing had been said of surgical diseases in which undue suppuration was caused by microbes, and estimating the mortality from these at five per cent., we had a grand total of ninety per cent. of all deaths to be attributed to disease of bacterial origin. It seemed, therefore, that Professor Brieger was right.

Bacteriology, he continued, had shown its principal fruit in surgery, and there could be no question that antiseptics had advanced this branch of medical science to its present high position. Antiseptics, however, was in reality nothing but the practical application of the three words—fermentation, putrefaction, and suppuration.

He then proceeded to give a *résumé* of the history of fermentation from the time when Lavoisier found

that sugar was split into carbonic acid and alcohol by the process of fermentation, which he thought to be simply chemical in character, knowing nothing of the animated life that was concerned in it. The discovery of the yeast-plant in 1835 threw a new light on the matter, and he gave some account of the researches of Ampère, Turpin, Franz Schultze, Liebig, Schwann, Helmholtz, Pasteur, Tyndall, and others since then in connection with this subject.

Fermentation he described as the decomposition of carbo-hydrates through the agency of the yeast-plant, and he compared the action of the latter to that of the bacteria which cause putrefaction and suppuration. Putrefaction was brought about by different kinds of microbes, fifteen or twenty varieties of which had now been discovered. There were, he said, two grades of putrefaction: The first was met with where there was but little oxygen present, and the products were water, carbonic acid, and ammonia, the process of decomposition being attended with little or no offensive odor. The second grade, or putrefaction proper, as generally understood, was seen where there was a large quantity of oxygen present.

Now the question arises, Dr. Knapp went on to say, whether suppuration and putrefaction are one and the same thing. Surgeons used the two terms promiscuously, and it seemed that suppuration, if not identical with putrefaction, was its consequence. There was, however, one cardinal point of difference, as would be mentioned further on. Having spoken of the experiments of Recklinghausen and others with the cornea of the frog, he referred to the common assertion of surgeons that, if all germs were excluded, suppuration would not take place. Personally, he had undertaken to investigate three special points in this connection, namely: (1) Does mere traumatism produce suppuration? (2) Do foreign bodies alone produce suppuration? (3) Do chemical agents of themselves produce suppuration?

In the first place, then, Does simple traumatism produce suppuration? In Berlin and at home he had made a number of experiments on the eyes of rabbits. If a wound were made by a perfectly clean instrument, he had found that it would heal by first intention, with no suppuration whatever; but if the wound were made with a contaminated instrument, suppuration invariably resulted. He now exhibited a rabbit in which extraction had been practised on one eye with a sterilized knife, and the other eye had been operated on with an instrument contaminated with pyogenic organisms. The result was that in one case the parts had perfectly healed, entirely without suppuration, while in the other profuse suppuration had been at once set up, and pronounced staphyloma finally produced. He said that he had performed a number of similar operations, and the results had always been the same.

One of the axioms on which antiseptics was based was that simple fractures never suppurate. While this was true, as a rule, there were rare exceptions; but it was a fact that when suppuration did occur, it was always in cases where some other focus of suppuration was found in the body. Whenever the individual was healthy, therefore, no suppuration would take place. In support of this statement, he mentioned the experiments of Becker, who, having made fractures in animals, injected pyogenic fungi into the ear, with the result of at once producing suppu-

ration, although the existing injury was only a simple fracture. Other similar experiments showed how ulcerative endocarditis and other suppurative processes could be produced by the introduction into the system of pyogenic organisms.

Dr. KNAPP then took up the second inquiry, Are foreign bodies by themselves capable of producing suppuration? The conclusion at which he arrived was, that if they were introduced antiseptically, they would produce no suppuration, and that they could remain indefinitely without giving rise to it. By way of illustration, he exhibited a rabbit, into the cornea of one of whose eyes he had introduced, by means of sterilized instruments, a piece of rusty hair-pin after having first brought the latter to a glow, for the purpose of destroying any organic matter which might be adherent to it. The result was, that no suppuration whatever occurred, although the foreign body had now been in the eye for quite a long time. Into the cornea of the other eye of the same rabbit he had introduced a piece of the same rusty hair-pin which had been dipped in fluid containing pyogenic fungi; and within twenty-four hours a violent phlegmon was set up which soon completely destroyed the eye. Still, the truth of the proposition that foreign bodies alone will not cause suppuration was not yet generally admitted, and Pasteur, in 1878, had stated that even if foreign bodies are introduced antiseptically, they were capable of producing suppuration. Whether he still adhered to the same view or not, Dr. Knapp was unable to say.

He then came to the third question, Do chemical agents by themselves produce suppuration? This, he said, was almost universally answered in the affirmative. Especially in the case of croton oil was it claimed that suppuration was caused without the intervention of germs. If this exception could stand, however, the theory of suppuration could not stand. It was a very difficult question to satisfactorily test in a practical manner; but the solution of the problem had been undertaken by four observers under very strict precautions. The results of their experiments went to show that chemical agents do not of themselves produce suppuration. In repeating some of these experiments Dr. Knapp had experienced much difficulty, especially as regards croton oil, on account of the extreme irritation caused by it. Oil of turpentine, however, he had found much more manageable. He had followed the method of J. Straus, which he proceeded to describe. On account of the practical impossibility of otherwise completely disinfecting the fur of the animal, he sterilized the skin of a rabbit by means of the actual cautery. Then, having made the injection of the chemical agent under the skin by means of sterilized apparatus, the opening made by the needle was sealed up again by the actual cautery. Some of the experiments were performed by means of a pipette, the opening in the skin through which its point was inserted having been made with a heated knife. With the experiments made with oil of turpentine and croton oil (although there were but five in which the latter was used) suppuration resulted in only ten per cent. of the cases. As a rule, there was coagulation of fibrin with some necrosis, but no suppuration; in the cases in which suppuration did occur, it was found that there were always germs present, on account of some imperfection in the performance of the experiment.

Roice, of Utrecht, had made the same experiments in connection with the anterior chamber of the eye; and this method of procedure had the great advantage of allowing the whole process set up by the chemical agent to be observed by the experimenter. Dr. Knapp had repeated Roice's experiments, and he had also in one instance introduced the chemical agent into the abdominal cavity. No appreciable effect was produced upon the animal, and when, two weeks later, it was killed, no pathological changes whatever could be observed at the autopsy. He here exhibited Koch's syringe, which he said he had found very useful in making his experiments. In his experiments upon the eye inflammation was caused, but no suppuration, even with croton oil; which he found could be used more satisfactorily when mixed with olive oil in the proportion of one to two. In some of the animals operated on the injection was made through the sclerotic. When the same chemical agent (either croton oil or turpentine) was introduced into the other eye in connection with pyogenic fungi, the most violent inflammation and suppuration were always produced.

He also made cultures from the two classes of eyes, using staphylococci principally for this purpose. From the eyes containing pus an immense number of microbes, with pus, resulted. But microbes (although no pus) were also obtained from the eyes from which pyogenic fungi had been excluded; and this required an explanation. The animals were killed, and the microbes were found not only in the eyes, but also in the kidneys and the blood; although there appeared to be none in the brain. It was evident, therefore, that the system had become infected through the suppurating eye; and the microbes which were found in the other eye had no doubt originated from this source. Hence it was determined to make the two different classes of experiments in two different series of animals, instead of operating upon both the eyes of the same rabbit. When the cultures were now made, no microbes were found to have come from the non-suppurating eyes. These experiments, he thought, were satisfactory and conclusive. In the eyes into which pyogenic germs were introduced in connection with the chemical agent, suppuration occurred, and microbes were found in large numbers; but in the eyes from which such germs had been excluded there were neither suppuration nor microbes. The results found in the latter were merely coagulated fibrin and fibrino-leucocytic exudation. Dr. Knapp thought, therefore, that so far as this whole series of experiments went, we were justified in formulating the proposition that suppuration is always produced by microbes; and hence there can be no suppuration without the intervention of these morbid agents.

What, then, is suppuration? he asked in conclusion. Just as in the case of fermentation, the microbe ought to enter into the definition. As previously remarked, fermentation was the splitting up of a hydro-carbon into similar forms through the agency of the yeast-plant. Putrefaction, again, was the similar splitting up of a nitrogenous substance through the agency of microbes. Finally, suppuration was likewise the splitting up of a nitrogenous substance through the same kind of agents. The difference between the two was, that in putrefaction the process always is concerned with dead nitrogenous substances, while suppuration always takes place in living ones. In this way the parallelism of these processes was established.

## THE BOSTON Medical and Surgical Journal.

THURSDAY, JANUARY 27, 1887.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this Journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 283 Washington Street.

Remittances should be made by money-order, draft, or registered letter, payable to

### PROTECTION OF THE PURITY OF INLAND WATERS.

SANITARIANS have long been impressed with the importance of protecting the purity of inland waters which furnish, or are likely to furnish, sources of domestic water-supplies; and manufacturers have been equally impressed with the difficulties attending such protection. In direct ratio to the density of the population, and the availability of the water-courses for manufacturing purposes, are the importance and the difficulty of protection increased. These two factors, density of population and availability of the water-courses reach their highest development in certain parts of New England, and preëminently in eastern Massachusetts; it is, therefore, natural that this State should be the first to attempt to grapple seriously with the problems involved.

A public Statute of 1878; the appointment and reports of three separate State commissions on drainage; the many excellent papers on pollution of water-supplies scattered through the volumes of the Board of Health reports almost from its origin in 1869, all testify to the growing appreciation of the magnitude and pressing nature of the problem.

In regard to certain watersheds all interests, the sanitarians, the legislators, the local authorities, the very manufacturers and inhabitants — are agreed that something should be done to provide for sewage and refuse otherwise than by emptying them into the streams and ponds; and yet from year to year plans, systems and charges are discussed and action is postponed.

The last legislature established another Act "to protect the purity of inland waters," the execution of which was intrusted to the State Board of Health. The principal duties of the Board as contained in that Act are summed up as follows:

- (1) To have the general care and oversight of inland waters.
- (2) To have the custody of maps, plans, etc., made for this purpose.
- (3) To recommend legislation and suitable plans for systems of main sewers.

(4) To cause examinations of the waters of ponds and streams to be made.

(5) To recommend measures to prevent the pollution of waters.

(6) To conduct experiments on the purification of drainage.

(7) To conduct experiments on the disposal of manufacturing refuse.

(8) To consult with and advise the authorities of cities and towns, or with others, with reference to water-supply and drainage.

(9) To consult with and advise manufacturers with reference to the disposal of manufacturing refuse.

(10) To bring to the notice of the Attorney-General all omissions to comply with existing laws.

The act further provides that authorities of cities and towns, and all others intending to introduce systems of water-supply or sewerage, shall submit to the Board outlines of their proposed plans or schemes in relation to these subjects; and that manufacturers intending to engage in any business, drainage or refuse, from which may tend to cause the pollution of any inland waters, shall also give notice to the Board of their intentions.

Under this Act the Board has made its first report to the Legislature, covering the first four months of the practical operation of the act from September 1st to December 31st, 1886. A chief engineer, an assistant and a consultant have been appointed, and the report of the engineer accompanies that of the Board.

Sanitary sins almost invariably have their origin in ignorance or selfishness, or in a combination of the two. As the Board of Health will be free from both of these influences, and we hope will know how to make itself felt as free from them, much may be expected from its intervention in these questions — provided it pursues them with the requisite zeal and tact, and provided the present legislature makes the necessary appropriation to defray the expenses entailed by the employment of expert engineers, chemists and biologists.

It is still an open question how far chemistry and biology are competent to establish the absolute safety of a given water-supply, but to be of positive value in determining the character of a body of water, of considerable size, subject to varying conditions, and its capacity for self-purification, examinations must be frequent and extended over sufficiently long periods of time, and such examinations involve expense. Moreover, it is only by such extended and systematic examinations that the rate at which the pollution of a stream makes progress can be determined.

Owing to their volume, and perhaps for other reasons, the Merrimac and Connecticut rivers were exempt from the operation of the Statute of 1878 for the prevention of the pollution of rivers and sources of water-supply. The Merrimac river, however, is at once the sewer and a source of water-supply of Lowell and Lawrence, two of the large cities of the Commonwealth and both among the large manufacturing centres of the world. In regard to this river the Board of Health reports to the Legislature that :

"The analyses of its water, made in 1873, 1879 and 1886, show that in 1873, when the amount of impurity in the water was sufficiently small to allow the water of the river, both at Lowell and at Lawrence, to be accepted as good drinking-water, the impurities then added by the sewage of Lowell and the refuse from the factories were so modified by flowing nine miles, and by being diluted by the increase in quantity of water, due to an increase of one-seventh of the drainage area, that the water at

Lawrence above the city was as good as that above Lowell; but in 1886 we find that, with substantially the same quantity of water flowing in the river, the percentage of impurities from animal and vegetable putrefaction, as shown by the albuminoid ammonia, has increased above Lowell by thirty-six per cent., and above Lawrence by fifty-seven per cent.; and that the impurities poured into the river at Lowell are now greater than the exposure to the air in flowing nine miles and the increased dilution can overcome, leaving the water above Lawrence with twelve per cent. more of impurities, due to animal and vegetable putrefaction, than that above Lowell, and fifty-seven per cent. more than it contained when the water-works were established at Lawrence, and now approximating the undetermined border line beyond which the water would be unfit for drinking.

"These results are obtained in September and October, when the quantity of water flowing in the river was about double the minimum quantity known to flow during a week of severe drought.

"At times of drought, and during the winter when the river is covered with ice, and the water having received the sewage of Lowell is not exposed to the air until it reaches the reservoir of the Lawrence Water-works, the percentage of impurities is probably increased, — notably above that given by the table; but of these conditions we have no analyses.

"In considering the table of analyses of the Merrimac river water still further, we find that, although polluted by the factories of Lowell and Lawrence, and such sewage as was there discharged, the analyses of 1873 showed the water above Bradford and Haverhill to be as good as that above Lowell; but this result no longer obtains, for the analyses of 1886 show the water above Bradford to have thirty-four per cent. more impurity than that above Lowell, and eighty-one per cent. more than it had in 1873, rendering it, unquestionably, an unfit source for the domestic water-supply of Bradford.

"This result is not unexpected; the same result has happened to every water-course in the State which happens to lie in the midst of a populous and growing district. A gradually increasing mass of pollution suddenly reaches a point at which the stream is no longer able to neutralize it, either by dilution or by any of the so-called processes of oxidation; and a condition of things is arrived at as disgusting as that of the Blackstone at Millbury, or of Alewife Brook in Cambridge and Somerville, or of the North River at Salem.

"In no one of these instances was the introduction of sewage a nuisance originally, and in no one of them would it have been possible to say in advance just where the saturation point would be reached."

The Board are of the opinion that the interests of the public require that, for one year at least, chemical and, when necessary, biological examinations should be made once a month, of all waters supplied for domestic purposes, by water boards, water commissioners and water companies within the State; and that thereafter such examinations should be made at intervals not exceeding six months.

They also believe that, with sufficient money to carry on experiments with scientific accuracy at some one of the public institutions of the State, where favorable conditions can be secured, very much can be learned in regard to the practicability of the disposal of sewage by irrigation fields under the conditions of climate to which we are subjected in these latitudes. Experiments are also contemplated upon the purification of sewage and refuse from industrial establishments. The Board estimates that the sum of \$30,000, will be required in the proper and advantageous discharge of its duties under the act.

We hope the sum will be appropriated, and it would not be amiss for physicians to impress upon their representatives in the Legislature the importance of the questions involved.

## ANTISEPTICS IN OBSTETRICS.

PROFESSOR RICHARDSON'S paper on the use of antiseptics in obstetric practice, and the free discussion thereof by the Obstetrical Society of Boston, both appearing in this issue of the JOURNAL, have placed this important subject so fully and clearly before our readers, that perhaps editorial comment is superfluous. Our admiration, however, of the scientific industry and clinical acumen which for years have been applied by the leaders in obstetric medicine to the investigation of the causes of puerperal fever, the media of its propagation, its prophylaxis and treatment, and our appreciation of the great benefits to mankind which will result from the universal acceptance and application of the now well-established principles of puerperal prophylaxis are such that we can forego no opportunity of contributing to the dissemination of what we believe to be the true principles of obstetric antiseptics.

While not underrating the importance of hygienic surroundings to puerperal women; while not ignoring the noxious effects of hospitalism and the consequent necessity of periodical fumigation and disinfection of hospital wards in addition to the usual attention to ventilation and general cleanliness, we are in accord with those who believe that puerperal fever is puerperal septicæmia and that it is propagated by contact, by infection,—by the introduction of septic germs from without to the inevitable abrasions and lacerations of the parturient canal.

This principle once accepted, the prevention of puerperal fever consists simply in taking due care that at the beginning of labor the vagina and genitalia of the patient are rendered aseptic, that during the labor and the puerperium all that comes in contact with the patient,—the examining finger, the hands of the nurse, catheters, forceps, needles, sutures, napkins and towels should be surgically clean; in other words, the possible infection by septic germs can be rendered impossible by sterilizing the micro-organisms before that which carries them comes in contact with the patient. The way and manner in which this can be accomplished has been admirably described by Professor Richardson.

We are aware that the advocates of rigid puerperal antiseptics meet with much opposition from those who, while admitting the great benefits accruing therefrom in lying-in hospitals, claim, nevertheless, that puerperal fever is comparatively rare in private practice and that unless some special reason exists therefore, rigid antiseptics is superfluous. Such opponents forget that there are minor and non-fatal forms of septicæmia; that, although death from septic causes is comparatively rare in private practice, fatal cases do nevertheless occur; that, apart from the fatal cases, there are many instances of tedious and prolonged convalescence with circumscribed peritonitis, phlebitis and other manifestations undoubtedly due to septic infection. Such cases cause the medical attendant much anxiety, and the patient undergoes the suffering,

confinement, and subsequent debility of a prolonged convalescence. Is it not worth while to prevent such complications by the application of rigid antiseptics to all cases? What valid objections can be adduced? The necessary precautions entail but slight expense; the trouble is very little to one who has once accustomed himself to the prescribed methods; the annoyance and possible danger of frequent douching is avoided, and the methods pursued are agreeable to the patient.

We have one word of caution, in connection with the use of the pad: let it not be conceived that the pad has any mystic power in the absence of other precautions. If unclean fingers and instruments are used during the labor, the pad might as well be dispensed with. Further, if for any reason the pad, which is in many respects a luxury, cannot be obtained, the customary napkin, if rendered thoroughly aseptic by immersion in a corrosive sublimate solution and subsequently dried before use, will fulfil the necessary requirement. The merit of the pad consists in the comfort it affords the patient in being soft, absorbent, and impervious; it requires less frequent changing than the napkin, and the patient is therefore less frequently disturbed. Moreover, the pad is destroyed after use, and the expense of washing thus saved is almost equivalent to the cost of the pad.

## FATAL EFFECTS FROM INODOROUS FUEL-GAS.

SEVERAL deaths and a large number of prostrations have recently been caused in Troy by the escape of fuel-gas from leaks in the mains; many of the cases occurred in houses which were not supplied with the gas, and it is supposed to have passed into the cellars through the ground or by means of sewer-pipes.

This gas, which on account of its cheapness and many practical advantages, has been very extensively used in Troy, is entirely inodorous, and is said to contain nearly thirty per cent. of the deadly carbonic oxide. It consists also largely of hydrogen, and is manufactured by the process of T. S. C. Lowe, of Norristown, Pa., from simple water; the water being first converted into steam in an ordinary steam boiler. Thence it is passed through one upright cylinder of boiler-iron lined with fire-brick and filled with fire-brick loosely thrown in. These fire-bricks are heated red hot by an air-blast upon gases derived from a second upright furnace of coal, which is made incandescent also by an air-blast. By the passage of the steam over the heated fire-brick, hydrogen, carbonic oxide and carbonic acid gas, are given off, and passing thence into the second furnace, the carbonic acid takes up one more part of carbon and becomes converted into carbonic oxide. The cost of manufacture is only about nine cents a thousand cubic feet of gas. When the accidents referred to occurred, the company very properly discontinued its production and it is likely

that the Legislature will prohibit its manufacture altogether in the State unless suitable safeguards can be devised in connection with its use.

Leaks necessarily occur in gas-pipes, and an inodorous gas, charged with carbonic oxide to a much less degree than this fuel-gas, ought not to be distributed.

Efforts to make this fuel-gas odorous by carbolic acid or naphtha—the latter making the fuel-gas similar to the illuminating water-gas—increase the expense beyond the point of profit.

#### THE TREATMENT OF STRICTURE OF THE URETHRA BY GELOSINE BOUGIES.

The treatment of urethral stricture by bougies of gelosine is an application of the principle whereby dilatation of the natural passages (like the cervix uteri) is effected by substances, which, like laminaria, swell under moisture.

Bedoin has lately reported to the Paris Société Thérapeutique satisfactory results in the use of gelosine bougies in urethral stricture. Gelosine is the Japan seaweed, which, in its dried state, undergoes a gradual and extreme degree of augmentation of volume when brought into contact with liquids, such as water, or the secretions of the human body.

Bedoin has devised cylindrical bougies of various sizes out of this alga, which, according to his experience (he has now tried them in several bad cases) when employed in stricture of the urethral canal effect very thorough dilatation, and with very little pain. He regards gelosine as fulfilling all the conditions requisite for the preparation of bougies which are strong and flexible, may be used with entire safety, and are sure to do their work thoroughly and effectually.

Such, at least, is the inventor's opinion. The introduction of tents into the strictured portion of the urethra was tried and abandoned about the middle of the last century, because of the serious accidents to which the method gave rise.

At the séance of the 7th of June, 1854, of the Paris Surgical Society, bougies of prepared sponge, as proposed by Professor Alquié, of Montpellier, were exhibited, but their use was evidently of short duration. Flexible ivory had been previously experimented with; bougies of this material possess, like sponge, the property of dilating in the canal, but, in practice, they dilated above and below the stricture faster than at the strictured portion, so that withdrawal was extremely difficult. Laminaria bougies were highly praised by Dr. Robert Newman in the *Medical Record* of July 1st, 1872.

The prolonged retention in the urethra of a bougie which fills the canal, keeping up only a passive, and not a constantly-increasing distention, is very likely to give rise to serious disturbances. Even the retention of a small instrument is an evil only to be suffered on special occasions. The constantly-increasing pressure of any slowly-dilating material within the urethra

is sure to prove an evil sooner or later, no matter how promising the first experiments with some new material may seem.

#### MEDICAL NOTES.

— Dr. James Davies states, in the *Therapeutic Gazette*, that the Druidic College of the twelfth century considered tannin the most potent of all the products of nature in producing sterility, and that tea-drinking, as practised by the public, undoubtedly acts in the same direction.

— Dr. J. J. Chisolm, of Baltimore, has been appointed Chairman of the Section of Ophthalmology in the Ninth International Medical Congress, in the place of Dr. E. Williams, compelled to resign on the ground of ill-health. Dr. Judson B. Andrews, Superintendent of the Hospital for the Insane, Buffalo, N. Y., has been appointed Chairman of the Section of Psychological Medicine, in place of Dr. John P. Gray, recently deceased.

— Dr. J. C. Reeve, of Dayton, Ohio, records in the *Philadelphia Medical News*, January 1, 1887, an instructive case of death from shock following the use of an aspirator needle. The patient had abscess of the liver, diagnosed before death, and confirmed by autopsy. The needle was introduced three inches in depth at a point two inches below the costal cartilages, and one inch to right of median line; the direction of its course being upward and backward. It punctured the liver but failed to reach the abscess which occupied the right lobe. No anæsthetic was used, and the patient was dead in ninety seconds after the operation. The heart was normal, and death was due to simple inhibition of its action.

— Dr. F. H. Darby, a prominent physician of Morrow, near Cincinnati, Ohio, was recently summoned to another town as a witness in a trial for wife murder. On taking the stand, he stated that he would answer any questions of fact that he could, but would not answer questions of opinion, that is, give expert testimony, without receiving an expert's fee. The judge told him such a fee could not be allowed and cited a decision of the Supreme Court of one of the States, that physicians could be compelled to give expert testimony without additional compensation. The doctor gave replies to all questions of fact but when asked to state "whether in wounds like this there would be immediate gaping or would the lips of the wound for a time remain in contact or nearly so?" he refused to reply. He was adjudged guilty of contempt of court but submitted to imprisonment for two days rather than recede from his position.

#### BOSTON.

— An order was introduced last week in the House of Representatives, which requires the Committee on Public Health to examine and report what legislation is necessary for protection against poisonous substances in wall and other papers, and in textile fabrics and other articles in common use.

— Another case of suicide from "Rough on Rats" is reported, in the person of a young woman nineteen years of age.

— The Boston Board of Health, through its chairman, Samuel H. Durgin, M.D., publishes the following summary of deaths in Boston, with principal causes, for the year 1886, compared with those for 1885; the whole population in each year being 400,000.

	1886	1885
Total No. of deaths from all causes	9,268	9,618
Annual death rate per 1000 inhabitants	23.17	24.04
Total No. from Zymotic diseases	1,644	1,879
Percentage of deaths from Zymotic diseases to total mortality	17.73	19.53
Total No. of Still-births	543	520
Total deaths of children under 1 year	2,110	2,156
Under 2 years	2,640	2,812
" " " "	3,166	3,466
Percentage of deaths under 5 years to total mortality	34.37	36.03
Total No. of deaths from diarrheal diseases under 5 years	605	621
Total No. of deaths from diarrheal diseases, all ages	705	723
Percentage of deaths from diarrheal diseases to total mortality	7.60	7.51
Alcoholism	29	52
Group	94	135
Carbuncle	3	7
Cholera Morbus	28	30
Cholera Infantum	444	461

## NEW YORK.

— During the progress of a fire on Vesey Street, which occurred January 21st, Superintendent Frederick Simmons, who attempted to cut a wire of the United States Illuminating Company, which caused obstruction to the firemen, was instantly struck dead by the force of the electric current with which it was charged.

— Dr. W. M. Lively, on January 20th, sent to the Bureau of Vital Statistics the certificate of death of Alice Downs, a colored woman, whose age he states to be 110 years, 11 months, and 9 days. She was born in Maryland, had never married, and had lived in New York for fifty-two years. The cause of death was pneumonia.

— Prof. E. L. Youmans, the well-known scientific writer and editor of the *Popular Science Monthly*, died January 18th, of fibroid phthisis, at the age of sixty-five. He was the intimate friend of Herbert Spencer, Huxley, and Tyndal. He studied medicine, and received the degree of M.D. at the University of Vermont, but never engaged in practice.

— At a meeting of the Section on Practice of the New York Academy of Medicine, held January 18th, Dr. E. Darwin Hudson, Jr., was elected Chairman for the ensuing year. A paper on "The Use of Quinine in the Pneumonia of Children" was read by Dr. Mary Putnam Jacobi, after which Dr. J. West Roosevelt read a paper on "A Short Account of our Present

Knowledge of Beriberi, with Observations on Cases recently in Bellevue Hospital." Dr. E. C. Seguin gave a report of three cases of beriberi in private practice, and Dr. H. H. Vineburg reported his observations of over one hundred cases in the Sandwich Islands.

— The annual meeting of the Saturday and Sunday Hospital Association was held January 18th, at St. Luke's Hospital. Among those elected members of the Executive Committee was Mr. Cornelius Vanderbilt. Mr. George McCollough Miller, who was re-elected President, in his address, suggested that the president of any auxiliary which should contribute \$1,000 or more should become a member of the Association for one year. The general agent, Mr. Cook, reported that the collections already amounted to about \$48,000, and that there was little doubt that the total would reach \$52,000, a considerable number of churches still remaining to be heard from.

— The popularity of the courses of lectures on anatomy, physiology, zoology, physical geography, and other scientific subjects, provided by the Legislature for the public school-teachers of New York and Brooklyn, and delivered by Professor Bickmore at the American Museum of Natural History, has been well attested by the increasing attendance from 121 at the opening of the course of 1884, to 140 at the opening in 1885, 286 in 1886, and 504 the present year. The lecture-hall is now entirely inadequate to accommodate those who wish to attend, and a bill providing for an enlargement of the Museum and better facilities for public instruction has been introduced into the State Senate.

## Miscellany.

## IS TETANUS CONTAGIOUS?

At the Société de Chirurgie, an interesting paper, as we learn from the *Lancet*, followed by discussion, was read by M. Larger, which seemed to show clearly that there were good grounds for believing in the contagiousness of tetanus. Four patients who had been treated in the Colmar Hospital were seized with tetanus at different intervals, and all died. The nature and severity of the wounds varied in each case from an amputation to a simple incised wound. The only thing common to them all was that the cases had all occupied contiguous beds. Tetanus is rare at Colmar. None of the patients had had anything to do with horses. A veterinary surgeon, M. Cagnat, had practised castration on horses for twenty-five years without a single case of tetanus. At the end of 1884, he removed with an écraseur a tumor of the testicle in a horse; the animal died of tetanus. Operations for castration practised with the same écraseur on five horses afterwards were followed by tetanus and death in all the animals. The écraseur was then submitted to disinfection by being heated to a high temperature. The instrument was afterwards used for fresh castrations, and without tetanus resulting in any of the animals operated on.

## LOCAL ANÆSTHESIA IN DENTAL SURGERY.

LAGRANGE, in the *Bulletin Gen. de Thérapeutique* (December 30, 1886), proposes the following means for the extraction of teeth without pain. He injects into the gums bordering on the teeth to be extracted a few drops (fifty centigrammes) of a three per cent. solution of carbolic acid, in which five centigrammes (or about a grain) of cocaine has been dissolved. The operation of extraction is quite painless.

His rules, as stated in the article in the journal aforesaid,<sup>1</sup> are as follows:

(1) Make a solution of cocaine (five centigrammes) in fifty centigrammes of carbolic solution (three per cent.).

(2) Inject thirty centigrammes of this cocaine solution into the gum outside of the decayed tooth, and twenty centigrammes into the gum inside of the tooth.

(3) The injection into the gum outside of the tooth must be made somewhat deeper than that made inside. This injection, moreover, has a much more marked anæsthetic action.

(4) In order that the insensibility may be complete, at least five minutes must elapse between the injection and the extraction.

(5) When roots are to be extracted, the injection should be made between the gingival border and the tooth, and the injection should penetrate as deeply as possible alongside of the roots.

(6) A little numbness and a slight shivering (*frémissement*) is apt to usher in the local anæsthesia determined by the injection.

## A PATHOGNOMIC SIGN OF CANCER OF THE STOMACH.

THE Paris correspondent of the *Lancet* says that at a recent meeting of the Société Médicale des Hôpitaux, a patient was shown who exemplifies the condition said by German writers to be characteristic of cancer of the stomach, a condition found by M. Debove to be constant in such cases, and which he proposes as a pathognomic sign of the disease. In malignant disease of the stomach, it will be found that hydrochloric acid is always wanting, whereas it lasts constantly during digestion in every other case. In M. Debove's patient, this absence of hydrochloric acid enabled a diagnosis to be made at a period when there was no other symptom of cancer, and the disease was looked upon as dyspepsia, an opinion shared by M. Debove himself until he had ascertained the composition of the gastric juice. Since the beginning of the year the man has been under observation, and the real nature of his disease, now constituted by a characteristic tumor the size of an egg, is no longer doubtful. In reply to questions, M. Debove said that he obtained the liquid for examination by means of the œsophageal tube, and that the test used for distinguishing the acids were those recommended by the Germans. A solution of gentian violet (1 to 5,000) gives a blue coloration with HCl. "*L'orange Poirier*" in saturated solution gives a red reaction with the same acid. Lactic acid is recognized by the increased yellowing of perchloride of iron, and by change in color of a mixture of perchloride of iron and carbolic acid, from amethyst-blue to yellow.

<sup>1</sup> Bull. Gen. de Thé., December 30, 1886.

## Correspondence.

## IN RE PASTEUR.

## ANOTHER SIDE OF THE REVEILLAC CASE.

MR. EDITOR.—In the *JOURNAL* for January 20th, an editorial deals with the case of young Réveillac, who died after having subjected himself to Pasteur's "intensive" method of inoculation. For the facts as presented in that editorial I will refer your readers to the editorial itself. To give those of them, however, who are debarred from access to French Medical journals, the opinions which were expressed by members of the Paris Academy of Medicine, in reply to Prof. Peter's assertions, seems but simple justice to Pasteur:

*Dujardin-Beaumetz* said (in brief): "M. Peter's case is interesting but not conclusive. He saw a man who had been bitten by a mad dog, who had been inoculated and who died frothing at the mouth, but this by no means proves that the patient died in consequence of the inoculation. It is very important to observe that many symptoms of rabies—ærophobia, hydrophobia, constant spitting,—were not seen in this patient, and also, as every one knows, that the paralytic form of rabies in man is absolutely exceptional. In every causal aspect this case is not proved, the less so in view of the fact that there has been a certain number of similar cases, in which it was shown that death was caused by anything but rabies; for example: the child who, bitten by a mad dog and inoculated by the "intensive" method, received one month later a blow on the ribs, experienced severe pain in this locality, went to bed, exhibited convulsive phenomena, which were attributed to rabies, and shortly after died. Animals inoculated with the spinal matter did not develop rabies. This child, then, did not die from hydrophobia. Probably succumbed to uræmic accidents. Scientific records show analogous cases."

*Brouardel* said: "I made the autopsy upon this child. It is sufficient to say that the diagnosis—rabies—had been made without examination of the urine and that the latter was very albuminous."

*Peter*, having reiterated symptoms which he considered as proof that his man died from rabies caused by the inoculation, *Dujardin-Beaumetz* replied: "A person may exhibit symptoms of hydrophobia without being mad," and he quoted cases in proof, then added: "In order to be certain that death is caused by rabies, all will agree with me that symptoms far more serious than those reported by M. Peter are necessary and I assert that the diagnosis of rabies ought not to be scientifically accepted until after positive inoculations with spinal matter from the subject supposed to have died of rabies, have been made."

*Chauveau* said: "With reference to paralytic hydrophobia I would say to M. Peter that it is not, as he believes, a hydrophobia of the laboratory. Ordinary rabies communicated by bites is often paralytic in animals. But suppose, in short—what is far from proved—that this man died mad; the conclusion in this particular case should then be, that the preventive inoculations were inefficacious and nothing more. This is very admissible because we all know that the immunity provided by the inoculations is never absolute. As to the assertion that rabies was communicated by these inoculations, that is another thing. I have just shown that the paralytic form of rabies proves absolutely nothing. I can say as much of the premonitory phenomena said to have taken their point of departure from the inoculated localities. These local phenomena are often missing; sometimes they are observed when rabies does not manifest itself. I have seen an example. In any case they have only an unimportant value and we can draw no conclusions whatever from their existence."

*Verneuil* said: "I think, in his communication, that M. Peter has abused the *post hoc ergo propter hoc*. When a person has been inoculated with an infectious malady and then dies, it is not always and fatally from this infectious disease. M. Peter's patient was bitten and inoculated.

Then, it is true, he died. But in view of the details of his illness, nothing is less certain than that the cause of his death was rabies. In fact everything is lacking in this case. Nothing has been said of temperature or spitting; there was no autopsy and no subsequent inoculation (with the spinal matter). Now, in order to draw conclusions, in a case of such gravity, absolute facts and not simple conjectures, are necessary. If we must abandon our illusions they will have to be wrested from us by facts of another sort of value than that of those we have just heard."

Thus ended the discussion, not one voice having been raised in support of Peter. The entire discussion may be found in *La Semaine Médicale* for January 5, 1887.

Yours respectfully, HAMILTON OSGOOD, M.D.

[We are happy to publish Dr. Hamilton Osgood's letter and glad to give all the comments made at the meeting of the French Academy upon the Réveillac case. Pasteur's side of the inoculation question has been frequently given in these columns, and it was with the purpose simply of giving "the other side" that we reproduced Professor Peter's statement in the editorial note referred to. His extravagant anti-microbism, as well as anti-Pasteurism, is too well known not to open his statement of any such question as that involved in the Réveillac case, to examination. Our editorial note referred to several of the points brought up in the debate, and, while one or two of our phrases may have been misleading, we by no means wished to indicate that Peter had proved his point.—Ed.]

# REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 15, 1887.

Deaths reported 2,312; under five years of age 164; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 436; consumption 364, acute lung diseases 440, diphtheria and croup 189, measles 103, diarrhoeal diseases 38, typhoid fever 35, cerebro-spinal meningitis 11, erysipelas 11, scarlet fever 19, whooping-cough 16, malarial fever nine, puerperal fever five. From typhoid fever, Philadelphia 11, New York nine, Baltimore five, Brooklyn, Boston, and Pittsburgh two each, Charleston, Lowell, Lynn and Lawrence one each. From scarlet fever, New York six, Brooklyn three, Philadelphia four, Boston three, Pittsburgh two, Baltimore one. From whooping-cough, New York seven, Brooklyn four, Philadelphia and Pittsburgh two each, Lynn one. From cerebro-spinal meningitis, New York five, Nashville and Lowell two each, Philadelphia and Lynn one each. From erysipelas, New York five, Philadelphia two, Brooklyn, Boston and Charleston one each. From malarial fevers, New York five, New Orleans two, Philadelphia and Baltimore one each. From puerperal fever New York two, Brooklyn, Boston and Nashville one each.

In the 20 cities and greater towns of Massachusetts, with a

population of 961,138 (population of the State 1,941,465) the total death-rate for the week was 22.02 against 22.61 and 21.77 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,033,817, for the week ending January 1st the death-rate was 25.1. Deaths reported 4,574; infants under one year of age 951; acute diseases of the respiratory organs (London), 573; measles 244, whooping-cough 90, scarlet fever 80, fever 56, diarrhoea 36, diphtheria 30.

The death-rates ranged from 16.8 in Blackburn to 36.0 in Halifax; Birkenhead 22.4; Birmingham 22.9; Bradford 19.5; Brighton 24.2; Hull 31.1; Leeds 28.5; Leicester 21.7; Liverpool 32.4; London 23.9; Manchester 32.3; Nottingham 21.3; Sheffield 20.1.

In Dublin 38.0.

For the week ending January 1st, in the Swiss towns there were 32 deaths from consumption, lung diseases 19, diarrhoeal diseases nine, diphtheria and croup six, measles three, scarlet fever three, whooping-cough one.

The death-rates were: at Zurich 5.7; Geneva 16.2; Basle 17.0; Berne 25.7.

The meteorological record for the week ending January 15, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending Saturday, Jan. 15, 1887.	Barom- eter.	Thermometer.				Relative Humidity.				Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>		Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 15, 1887, TO JANUARY 21, 1887.

FORWOOD, W. H., major and surgeon. Ordered for duty at Fort Meade, D. T. S. O. 5, Department of Dakota, January 14, 1887.

BROOKS, JOHN, major and surgeon. Ordered for duty as post-surgeon at Fort Monroe, Va. S. O. 10, Division of the Atlantic, January 14, 1887.

GARDNER, W. H., major and surgeon. Ordered for duty as post-surgeon at Fort McHenry, Md. S. O. 10, Division of the Atlantic, January 14, 1887.

POPE, B. F., major and surgeon. Ordered for duty at Fort Clark, Tex. S. O. 15, A. G. O., January 19, 1887.

#### SOCIETY NOTICES.

SUFFOLK DISTRICT MEDICAL SOCIETY. SURGICAL SECTION.—There will be a meeting of this Section at 19 Boylston Place, Wednesday evening, February 24, at eight o'clock. Dr. David W. Cheever will report the following cases illustrative of the Surgery of the Abdomen. I. "Deep Abscess of Abdomen in a Child: Abdominal Section: Drainage: Recovery." II. "Abscess in Abdomen (Perityphlitic?) in a Young Man: Abdominal Section: Drainage: Tapping through Rectum: Recovery." III. "Pyo-Nephritic Abscess after Labor: Laparotomy: Drainage: Partial Recovery." IV. "Pelvic Abscess in a Female: Exploration through Abdominal Wall: Dilatation of Urethra: Drainage through Bladder: Partial Recovery." V. "Volvulus: Abdominal Section: Artificial Anus: Death." VI. "Herniotomy: Mortification of Bowel: Resection and Intestinal Suture: Death." VII. Stoppage of Bowels: Recovery without Operation." VIII. "Stoppage, and Peritoneal Irritation: Recovery without Operation."

GEORGE H. MONKS, M.D., Secretary.

#### ERRATUM.

On page 61, second column, line twenty-nine, of JOURNAL of January 20th, instead of "disappoints" read "often disappoints."

#### APPOINTMENT.

At the adjourned annual meeting of the Boston Society for Medical Improvement, Dr. O. F. Wadsworth was chosen President for the ensuing year.

#### DEATH.

Died at New Bedford, Mass., January 14, 1887, William Alexander Gordon, M.D., M.M.S.S., in the seventy-eighth year of his age.

#### OBITUARY.

##### ESTES HOWE, M.D.

Dr. Estes Howe died at his home on Oxford Street, Cambridge, Mass., January, 1887, at the age of seventy-two years and six months. He was a native of Northampton, and was a son of Judge Howe of that city. He was graduated at Harvard

in 1832 and subsequently studied medicine, being for many years a successful practitioner. At one time he resided in Cincinnati. Since coming to Cambridge he had represented the city in the Senate in 1859 and 1871, and was at one time a member of the Cambridge Water Board. Of late years he had not actively practised his profession. For thirty-five years he had been Treasurer of the Cambridge Gas-Light Company.

##### WILLIAM PERRY, M.D.

The oldest living graduate of Harvard College died January 11, 1887, at Exeter, N. H., in the person of Dr. William Perry. He was born at Norton, Mass., December 20, 1788, and was therefore at the time of his death aged ninety-eight years and twenty-one days. He was a member of the class of 1811 of Harvard. After graduating from Harvard Dr. Perry studied medicine with the eminent Dr. John Warren, and soon after settled at Exeter, where he enjoyed a long and successful practice. He was one of the first persons to advocate a State insane asylum. He attended church constantly from the time when, four years old, he went barefooted, to about six months ago. He leaves two sons, Dr. William G. Perry, the oldest practicing physician in Exeter, and John L. Perry, until within a few years connected with the *Cincinnati Gazette*, who now devotes his time to literary work. He was grandfather of Sarah Orne Jewett, the authoress. He was sole survivor of the passengers on Fulton's first steamboat passage down the Hudson River, August 10, 1807, being at that time on his way from Union College, Schenectady, N. Y., to Harvard College, which he had just determined to enter. On reaching Albany he found that none of the regular river boats would start for several days, but that the "Katherine of Clermont," Fulton's boat, then on her trial trip, had just reached Albany and would start on her return next day. He took passage on her as far as Kingston. After she landed him she travelled but a few miles before her boiler burst and she was laid up for repairs several days. Dr. Perry had retained his health up to the present winter.

#### BOOKS AND PAMPHLETS RECEIVED.

Transactions of the American Ophthalmological Society. Twenty-Second Annual Meeting. New London, Conn., 1886. Boston: Published by the Society. 1886.

Annual Report of the Supervising Surgeon-General of the Marine-Hospital Service of the United States. For the Fiscal Year, 1886. Washington, 1886.

Some Medico-Legal Cases under State and National Laws. By B. Joy Jeffries, A.M., M.D., of Boston. From the Transactions of the American Ophthalmological Society, Twenty-Second Annual Meeting, 1886.

Über subdiaphragmatische Echinokokken und deren Behandlung. Vortrag nebst Demonstration von drei geheilten Fällen gehalten im Verein für innere Medizin am 1. November 1886. von Dr. Leopold Landau, Dozent der Gynäkologie an der Universität Berlin. Berlin, 1886.

Report on Diseases of the Rectum. By Joseph M. Matthews, M.D., Professor of Principles and Practices of Surgery and Diseases of the Rectum in the Kentucky School of Medicine, Louisville, Visiting Surgeon to Louisville City Hospital, etc. Read before the Kentucky State Medical Society, at Winchester, June 24, 1886. Louisville, Ky., 1886.

## Lecture.

MULTIPLE NEURITIS AND ITS RELATION TO CERTAIN PERIPHERAL NEUROSES.<sup>1</sup>

BY M. ALLEN STARR, M.D., PH.D.,  
Professor of Nervous Diseases, New York Polyclinic.

THE discovery of a new disease is never made suddenly. It is a gradual process, and certain stages in the progress towards its complete recognition may be observed. There is first the period of clinical observation, when isolated cases of an unfamiliar and mysterious affection are recorded as curiosities. To this succeeds the period of diagnosis, when, by a comparison of the now numerous cases, a clinical picture of the disease is gradually filled out. In this stage there is much to impede the progress of discovery. For not content with an analysis of symptoms, and a grouping of cases, the majority of observers offer theoretical explanations of the nature of the new affection, and an element of speculation enters, which often obscures the facts. There is, however, a real progress in this period, for it is characterized by inductive reasoning from fixed data, and, as a result, reliable conclusions are reached, which make a diagnosis possible. The third period is that of pathological discovery, where the morbid changes lying at the basis of the disease are accurately ascertained. In this stage erroneous theories are eliminated, true explanations for various symptoms become self-evident, and the exact nature of the affection is determined. The disease has now a status of its own. And at first this might seem to be the final stage in the progress of discovery. It is not. There remains a period of etiological classification, when conditions, formerly supposed to be dissimilar, are found to have a common basis, when the pathological changes are ascertained to be the same although the clinical pictures have varied, and when classification of the various forms is rendered possible and a definition of the disease is reached.

Such a gradual advance toward general recognition is well illustrated by the history of multiple neuritis, which is to engage our attention at the present time.

I think we may claim that one of the first cases presented was by an American physician, Dr. James Jackson, of Boston, in 1882.<sup>2</sup> In a paper "On a Peculiar Disease Resulting from the Use of Ardent Spirits," which he named arthrodynia, he gives a most graphic picture of what we now know to be one form of multiple neuritis.

He says, "This disease comes on gradually. It commences with pain in the lower limbs, but especially in the feet, and afterward extends to the hands and arms. The hands may be affected first in some instances, and in all cases in an advanced state the pain is more severe in the feet and hands than in the upper part of the limbs. The pain is excruciating, but varies in degree at different times. It is accompanied by a distressing feeling of numbness. After the disease has continued a short time, there takes place some contractions of the fingers and toes, and inability to use these parts freely. At length the hand and feet become nearly useless, the flexor muscles manifesting, as in other diseases, greater power than the extensors. The whole body diminishes in size, unless

it be the abdomen, but the face does not exhibit the appearance of emaciation common to many visceral diseases. The diminution is especially observable in the feet and hands, and some time the skin of these parts acquires a peculiar appearance. The same appearance is noticed in a slighter degree in the skin of other parts. This appearance consists in a great smoothness and shining, with a sort of fineness of the skin. The integuments look as if tight and stretched, without rugæ or wrinkles, somewhat as when the subjacent parts are swollen, but the skin is not discolored. Yet in this disease there is not any effusion under the skin, and the character which this assumes arises from some change in the organ itself. The most characteristic symptoms are manifested in the limbs, but the pain is not limited to these — and other symptoms are exhibited in other parts. The pain sometimes shoots suddenly up one or both legs, and in one case it frequently passed up the back and then forward to the pit of the stomach. The functions of the stomach are always impaired. The mind is weakened. Sleep is prevented by pain. I believe that this disease is always fatal when the use of spirituous liquors is not abandoned before the powers of the digestive organs are greatly impaired."

It is hardly possible, even at the present day, to add to this description, which portrays in strikingly vivid language the main features of one form of multiple neuritis.

The next observations of importance in establishing a clinical picture were made by Magnus Huss, who, in his work upon chronic alcoholism, in 1852, gave a very complete description of alcoholic nervous symptoms, dividing the cases into paralytic, anesthetic, convulsive, epileptic, and hyperæsthetic forms.

In 1855 the great work of Duchenne was published,<sup>3</sup> and in it a number of cases are recorded which we now recognize as multiple neuritis. In these cases there were sensory disturbances, consisting of pain, numbness and loss of sensation; motor disturbances consisting of paralysis, with atrophy, especially marked in the distal parts of the extremities, and attended by a loss of faradic contractility in the paralyzed muscles; and cyanosis, coolness, and increased sweating in the affected limbs. Duchenne grouped these cases together under the title, "Paralysie Générale Spinalé Subaiguë Ascendante," because he thought a gradual advancing lesion in the spinal cord, from below upward, would explain the symptoms. It is true that he found no microscopic change in the cord in the only case in which he made an autopsy. But when, under the leadership of the French school, from 1860 to 1865, the microscopic appearances in nervous lesions began to be studied, the hypothesis of Duchenne at once appeared to be verified, for it was found that such symptoms as numbness, pain and anesthesia were associated with lesions of the posterior columns of the spinal cord. And it was also proven that atrophic paralysis was caused by a degeneration of the ganglion-cells of the anterior gray horns of the cord, not necessarily visible to the naked eye. It seemed an easy step to the conclusion that when these symptoms occurred together, the entire spinal cord was the seat of disease, and that wherever they occurred a spinal lesion was progressing. The pathology of this form of paralysis appeared to be definitely ascertained, and for many years the fallacy of such a conclusion was

<sup>1</sup> Lecture I of the Middleton Goldsmith Lectures, delivered under the direction of the New York Polyclinic Society, Jan. 25, 1887.  
<sup>2</sup> New England Journal of Medicine and Surgery, Vol. xi, p. 351.

<sup>3</sup> Electrization Localisée.

not detected. All atrophic paralysis was invariably referred to spinal lesions, because spinal lesions may cause atrophic paralysis.

But facts rarely accommodate themselves permanently to theories, and after a time a mass of very unwieldy facts began to accumulate. Cases of atrophic paralysis without spinal lesion were observed, and these, threw doubt upon the theoretical pathology. The period of true pathological observation had begun and gradually went on to completion. In 1864 Dumeuil reported the following case, which deserves to be cited, as it is the first in which an autopsy established the existence of a wide-spread disease in the peripheral nerves as a cause of sensory motor and atrophic symptoms.

*Observation I.*—A tailor, aged sixty-one, after suffering from pricking in the toes for two weeks, was suddenly taken with weakness in the left arm and right leg, and, a few days later, by the same paresis in the left leg. Within five days he could not stand or walk. The paralyzed feet hung flaccid, and were totally paralyzed; the thighs could be moved freely. Anaesthesia was found on the right sole and calf, and on the left foot and outer side of the leg. In the muscles of the hands and forearms a considerable atrophy, with paralysis, developed. The faradic contractility was abolished in the paralyzed muscles. He complained of a painful numbness in the paralyzed limbs up to the knees, and limited to the hands.

No improvement; death in four and a half months.

*Autopsy:* Spinal cord and nerve roots were normal. The finer nerve-branches in the legs and hands were degenerated, only a small number of nerve-fibres being found. Single fibres showed no continuous myelin sheath; but this was segmented and granular. There was an increase of connective tissue, and many fat cells in the nerves.\*

This case being of an anomalous character excited very little attention. Two years later, however, Dumeuil reported another, and published an elaborate article on peripheral paralysis, in which he said: "My own observations have convinced me firmly that many paralyzes of obscure origin are caused by true spontaneous neuritis." . . .

Singular as it may seem, an interval of ten years elapsed before another case of similar nature, accompanied by a record of *post-mortem* examination, appeared. Then Eichhorst, of Berlin, reported the following interesting history:

*Observation II.*—A female, aged sixty-six, after suffering daily for two weeks from a chill, fever, and sweat, attended by malaise, anorexia, and constipation, noticed an oedematous swelling of both feet and legs, and complained of pain in the abdomen. A week later, on admission to the hospital, these symptoms continued. The urinary examination was negative. Three days after admission she suddenly felt a severe boring pain in the left leg, shooting into the toes, and at the same time a profuse sweat broke out over the calf and back of the foot. A few hours later a total paralysis was found in the muscles supplied by the peroneal nerve, with a marked anaesthesia. The electric reaction, at first preserved, was found two days later to be gone. After six days, during which she had no further chills, a paralysis of the anterior tibial nerve developed, and soon after of the posterior tibial nerve also. One week later entire paraplegia of the

legs, with anaesthesia, severe pains, continual sweating, increasing oedema, and loss of the tendon reflexes had ensued. There followed a paralysis of the left, and soon after of the right, radial nerve. Moderate fever continued and albuminuria appeared. Three weeks after her admission sudden blindness developed, the ophthalmoscopic appearance, being at the time normal; the patient then lay in bed with eyes closed, unable to move a limb. The extremities perspired constantly, and were tender, any pressure on nerve-trunks being very painful. In the face there was no trouble, and the senses were normal except that of sight. No trouble in swallowing. Nothing abnormal about the viscera during the entire disease. No irregularity of pulse or respiration. Death occurred on the forty-fourth day of the disease.

*Autopsy:* Spinal cord absolutely normal. The nerve-trunks in the bicipital grooves appeared intensely red to the eye, the perineum being discolored and the endoneurium blood red. The same appearance was noticed in the large nerve-trunks of the arm in their course, as well as in the left tibial nerve. The microscopic examination showed a remarkable distention and tortuosity of the blood-vessels of the perineum; the vessel-walls were thickened, their nuclei increased. In the vicinity of the vessels a large number of lymphoid cells were found, which everywhere followed the vessels and infiltrated the connective tissue. There were also numerous fatty cells. The connective-tissue fibrillae of the perineum were thickened, shining, and swollen; their nuclei were increased and partly infiltrated with fat granules. Similar changes now seen in the endoneurium, namely, numerous extravasations of blood, which separated the nerve-fibres and compressed them. The nerve-fibres showed marked degeneration, especially those lying next the endoneurium, consisting of disintegration of the myelin sheath, and a distention and spindle-shaped swelling of the individual nerve-fibres. The nuclei of the sheath of Schwann were not increased in number, but the protoplasm about them was coarsely granular and opaque. The cells of the endoneurium were everywhere wanting, being replaced by fatty granular cells, even between the uninjured fibres.<sup>5</sup>

This is the first case to be found in which the microscopic appearances are described with sufficient detail to be satisfactory. It is to be noticed that here the lesion was an acute inflammation, and was, apparently, a diffuse one, both interstitial tissue and nerve-fibrils being involved in the process. That it was primarily an interstitial inflammation, and that the affection of the nerve-fibrils was secondary, due to pressure of the products of exudation, is clearly seen in the fact that those fibres were more seriously affected which lay near vessels, while the deeper fibres in large bundles were not at all degenerated. The appearance of the fibres was such as occurs in any degeneration from pressure. There is no reason, therefore, to believe that the process began diffusely.

As to the symptoms in this case, it is to be remarked that they were ushered in by an acute febrile movement with chills, and that severe pain was an early and prominent symptom; also that oedema and sweating were present; and the optic nerves were involved.

The clinical picture in the following case of Joffroy, published three years later, was somewhat different, as was also the pathological condition.

\* Dumeuil. Gaz. Heb., 1864, p. 263, and Gaz. Heb., 1886, No. 4.

<sup>5</sup> Eichhorst. Virchow's Archiv, Bd. 80, p. 265, 1876.

**Observation III.**—A washerwoman, aged thirty-three, in the last stage of phthisis, was admitted to the hospital on March 5th. In February she had noticed a rapidly increasing weakness of her legs, and at the time of admission she could not walk or raise her feet from the bed. She could flex the knees but not extend them. There was no contracture, and the muscles were relaxed and flabby. Sensation to pain, temperature and pressure impressions, was normal, but the muscular sense was lost, and reflexes were diminished. She showed such a degree of mental weakness that tactile sense could not be tested. She had no shooting pains, no loss of control over bladder and rectum, no bedsores. Two weeks later the arms became involved in the paralysis, and atrophy, incoordination, and loss of muscular sense, with fibrillary motions, developed within a few days. There was great diminution of faradic excitability in all the paralyzed muscles. At the end of ten days the arms were entirely powerless, but retained their sensibility. On April 7th she died.

**Autopsy:** A chronic meningitis of the brain explained the mental symptoms. The spinal cord was normal. The nerves appeared normal; but microscopic examination showed very marked degeneration in all the nerve-trunks, but especially in the sciatic, radial, and ulnar nerves. There was a segmentation of the myelin sheath, which at places was reduced to a finely granular mass. Many sheaths of Schwann were filled with this mass; others were empty. The nuclei of the sheaths of Schwann were increased in number. All the spinal nerve-roots were normal. The changes in the nerves were followed down into the fine terminal branches in the thenar muscles. The muscles were atrophied, and showed fatty degeneration.<sup>4</sup>

Here, in contrast with the preceding case, it is to be noted that the lesion was not attended by congestion of the nerves, or by any exudation of lymphoid cells, or by marked interstitial changes. The affection was a true parenchymatous inflammation, with degeneration of the myelin sheath, and axis cylinder. As a result, the microscopic appearance of the nerves was not such as to attract attention, and it required a microscopic examination to demonstrate the changes present. Joffroy, who reports this case as one of general spontaneous neuritis, finds the lesion identical with that observed in cases of localized neuritis occurring from cold, from lead-palsy, or as the sequel of the infectious diseases. In regard to the symptoms, also, the case contrasts strongly with the preceding one. The patient had phthisis. The disease advanced more slowly. Pain was absent, and the sensory symptoms were by no means prominent, the muscular sense being the only one affected.

In 1880, the following cases were observed by Leyden in the Charité Hospital of Berlin, in both of which changes were found in the peripheral nerves. They are cited because they not only enlarge our clinical picture, but confirm the pathological conditions already described. . . .

When the characteristic features of a new disease have once been clearly pointed out, it is remarkable to observe how rapidly cases of it begin to be recognized. In the two or three years which followed the appearance of Leyden's article, numerous cases of multiple neuritis were reported in the journals; and

many physicians, reviewing their records, recognized, in cases previously obscure or imperfectly diagnosed, typical pictures of the new disease. It may be well to consider a few of these cases, in order to complete our clinical knowledge of the affection.

**Observation VI.**—A female, aged thirty, of intemperate habits, but otherwise in good health, after suffering from fornication, coldness, and pains in her feet and legs for some months, noticed an oedema of both legs. This increased rapidly after a few days, and the swollen limbs became painful to touch or pressure, and were the seat of severe, lancinating pains, which were worse at night. Within a month the same symptoms appeared in the arms and hands, and a marked hyperæsthesia developed in all the extremities, as well as a rapidly-progressing paralysis; so that, on admission to the hospital, six weeks after the appearance of the oedema, it was impossible for her to lift her limbs from the bed, or to extend her hands and fingers. The movements in the distal portions of all the extremities were much more impaired than those near the trunk, and in the paralyzed extensor muscles the faradic excitability was almost abolished. Heart and kidneys normal. She had some fever, and was delirious at night. The symptoms increased rapidly; the paralysis became total; respiration became difficult; the heart rapid, and a week after admission to the hospital she died.

**Autopsy:** Tubercles in the lungs. Brain and cord were normal. Nerve-roots were normal. In the nerves of the extremities marked degeneration was found, especially in the radial and tibial nerves. By the side of a small number of empty sheaths were found fibres, whose myelin was segmented and in drops, separated by empty spaces. The axis cylinders were indistinct. There was no increase in the nuclei of the sheath of Schwann.

In discussing the case, Dr. Lanceraux made the diagnosis of alcoholic paralysis, assigning the lesion to the nerves, and differentiating it from a myelitis or a meningitis. In so doing, he criticised the view of Wilks and Lockhardt Clarke, who still considered alcoholic paralysis as a central disease. He cited another case, very similar, of a female aged thirty-three, in which the symptoms were pains, hyperæsthesia, tenderness, paralysis, with atrophy in the extremities, but in which oedema was not so marked, and came on quite late in the course of the case. The same lesion were found. To these he added two cases, in which the patients manifested the same symptoms, but had never drunk. They were both, however, sellers of varnish, and lived day and night in an atmosphere permeated by alcoholic vapor, from which he concludes that chronic alcoholic poisoning can occur by absorption through the lungs—a valuable observation, but hitherto not confirmed.<sup>7</sup>

The following case was reported by Granger Stewart, together with two other cases, which resulted in recovery:

**Observation VII.**—A male, aged thirty-one, noticed during August, 1880, a weakness of the legs, and during the following month a pain of a prickling character in the legs and feet. These increased in intensity, and in October a similar feeling came on in the fingers and hands, accompanied by a loss of power and stiffness. When seen, in November, he had a tingling

<sup>7</sup> E. Lanceraux. De la Paralysie Alcoolique, Gaz. Heb. de Méd., 1881, p. 120.

<sup>4</sup> A. Joffroy. Arch. de Phys. Norm. et Path., 1879, pp. 172-198.

pain in both legs, from the knee to the back of the foot, with numbness and feeling of cold in the toes and plantar surfaces, so also in the hands, to a less extent. No girdle pain or formication. Sensibility to touch was diminished in the legs and hands. Transmission of impressions was delayed. Sensibility to heat, tickling, and pain were all diminished, as was also the muscular sense in the feet. There was no nystagmus, although he complained of things dancing before his eyes. Sight was normal. There was no incontinence of urine or feces. The skin reflexes were absent in the soles, but normal in the abdomen and groins. The knee-jerk was absent. Voluntary motion was greatly impaired in legs and arms, and attempts to use the muscles caused pain. Electric irritability of the muscles, and sensibility of the skin was much diminished. There was no vaso-motor or trophic changes. His mental condition became changed during his stay, his memory was impaired, and he seemed drowsy. A month after his first examination he died of pneumonia.

Autopsy by Dr. D. J. Hamilton: The median, ulnar, and tibial nerves showed great changes. With a low power of the microscope, the bundles of fibres appeared to be affected by fatty degeneration. With a high power, it was found that the axis cylinders were swollen, so as to form a number of fusiform bodies in the course of the nerve-tubes. These, at parts, were divided into a number of round, homogeneous, colloid bodies. When set free, these bodies underwent a fatty degeneration, forming compound granular corpuscles. In some fibres the axis cylinder was totally destroyed, nothing but a quantity of fibrous tissue remaining. The cords of the brachial plexus and the sciatic nerves were normal. Slight evidence of secondary sclerosis in the spinal cord was found in the columns of Goll, and in the direct cerebellar columns. Its origin could not be explained.\*

It must not be supposed, from the fact that all the cases so far cited were fatal, that death is always the result in multiple neuritis. This is very far from the truth, and probably, if the mortality had been greater, the pathology of the disease would not so long have eluded search. The fatal cases have been brought together, in order that the pathological appearances observed might be noted and compared, and might become somewhat familiar by repetition. It is time to enter upon the more careful study of their pathology, and so, for a time, let us leave the clinical features of the disease.

[The lecturer then reviewed the normal anatomy of a nerve, before proceeding to discuss the changes occurring in inflammations of the nerves. This part of his subject was profusely illustrated.]

#### THE PATHOLOGY OF MULTIPLE NEURITIS.

In studying the pathological processes which occur in multiple neuritis, it is necessary to keep these various elements of the normal nerve in mind, since each element is subject to changes. The exact character of these changes is best understood by observing the results of nerve-degeneration artificially produced in animals. And a study of this will not be out of place here, for, as we shall see, the changes occurring in multiple neuritis correspond quite exactly to those produced by experimental degeneration.

In considering the pathology of degenerative neur-

itis we enter at once upon a mass of controversial statements. It would seem to be a simple matter to establish, by observations upon nerves which had been experimentally compressed or severed, the changes which ensue in nerve injuries. But, as a matter of fact, there is, perhaps, no field of experimental pathological inquiry in which the results have differed more widely. In the first place, it is probable that the rapidity and even the character of the changes differ in different animals. Secondly, various methods of investigation, of hardening, dissecting, and staining the nerves, seem to have resulted in the production of different appearances. And, lastly, it is by no means certain that a uniform pathological process goes on after experimental lesions. After a lesion of a nerve-trunk, a process of degeneration sets in at the point of injury, and involves a small portion of the central end and the entire peripheral part of the nerve, from the seat of injury onward. This process may be more or less complete, and may, or may not, be followed by a second process of regeneration in the diseased nerve. It is necessary to distinguish between the degenerative and regenerative processes; and, inasmuch as it is affirmed that they may proceed simultaneously in various parts of the same fibre,\* it is not strange that the confounding of the two should have increased the confusion in the statements.

The majority of writers upon nervous diseases and upon general pathology seem to have followed Ranvier closely, without any mention of the fact that other authorities differ from his conclusions. It will be necessary here to present the various views which are held.

[The process of degeneration was then described in detail, and the differences of opinion pointed out.]

Authorities seem to agree that the same results follow a division of a nerve that are observed after its compression, with the difference that at the point of section the myelin runs out of the sheath of Schwann. The cut ends become swollen into bulbous extremities by a growth of connective tissue.

Whether a true union of the divided ends ever occurs is still a matter of uncertainty. The majority of authorities, following Ranvier, affirm that while a primary coaptation of the ends by an exudate which is secondarily transformed into connective tissue, may occur and hold the ends in position, no true primary union of nerve-fibres is possible, and under all circumstances the degenerative process already described goes on to completion. Glück, however, claims to have observed an actual union of the two ends, with re-establishment of function, at a time too early to have admitted the occurrences of degeneration and regeneration, and Walberg, approaching the subject from the surgical side, and considering the results of nerve-suture, inclines to the same view.

In the midst of such contrary statements, what conclusion can be reached as to the actual facts? It seems evident that but one conclusion is certain, namely, that under different circumstances different processes occur. The various observers are equally trustworthy. It is impossible to choose one set of conclusions rather than another, or to rely wholly upon one series of experiments, however capable the observer may be, for they all rest upon repeated observations. It is undoubtedly true that in some cases

\* Granger Stewart. Edinburgh Medical Journal, April, 1881.

\* E. Neumann. Ueber De- und Regeneration der Nerven, Arch. f. Mikro. Anat., xviii.

the degeneration process, so graphically pictured by Ranvier, from the beginning segmentation of the myelin down to the final result in the connective-tissue strand, the relic of the empty sheath of Schwann does go on; while in other cases of a less serious nature the distinction is less complete, and there remains a fibre consisting of a sheath of Schwann, containing a granular mass which may be either an axis cylinder or a mass capable of developing into an axis cylinder under favorable circumstances. If this is the case, we can affirm that brilliant surgical successes, with rapid restoration of nerve function after suture, are possible when the partial degeneration is present, but are impossible when the total destruction of the nerve-fibre has occurred. And statistics show that there is a certain percentage of operation which fail of any result, though repeated on the same nerve. . . .

It is evident that future research should be directed, not so much to determine which of the processes described occurs, as to settle under what circumstances the one is produced rather than the other. And such research will have an eminently practical bearing, inasmuch as it will also demonstrate under what circumstances nerve-suture is likely to be attended by success.

#### THE PROCESS OF REGENERATION.

After the process of degeneration has gone on for some time in the nerve-fibre, it may cease, and the process of regeneration may begin. With regard to the method of this process two widely divergent views are held. Ranvier<sup>10</sup> and his followers claim that the new nerve is wholly a product of the central end of the injured nerve, growing out from it and making its way along the track of the peripheral end, which takes no active part in the process. Neumann and Mayer, on the contrary, believe that the regeneration goes on in the peripheral end of the cut nerve, segment by segment being formed successively, beginning at the point of injury and proceeding outward, the entire nerve being built up by the union of each distal segment with the one lying centrally to it, until this process has reached the end.

[To these various views was given a more exact statement accompanied by numerous illustrations.]

The process of degeneration in the nerves, consequent upon the destruction of the ganglion cells from which they arise (the so-called Wallerian degeneration) differs in no respect from that ensuing upon compression or division, excepting that in the latter case only the distal part of the divided nerve undergoes the pathological change, while in the former it is the entire nerve that is affected. And in the changes described in multiple neuritis the same progress of events and the same varieties of determination are observed.

When the cases of multiple neuritis are examined from a pathological standpoint, several varieties may be distinguished. In some of the cases, and these are the most numerous, there is a parenchymatous inflammation in the nerve-fibre only visible to the microscope. At the outset of this inflammation the myelin sheath appears slightly swollen, is less homogeneous, and from a difference of refractive power is less translucent. It then becomes split up into segments of different length and form, the segmentation occurring preferably at the incisures of Schmitt, while the incisures at other parts disappear. Between these segments of myelin, a finely granular protoplasm is seen, in which

new nuclei are found. These nuclei probably are the cells of Rosenheim which have emigrated, although a few near the nucleus of the sheath of Schwann may be due to its division. In some fibres the axis cylinder may still be preserved. In others it is broken at the same places as the myelin. At the next stage of the process the changes are more marked. The myelin is now reduced to a series of small globules surrounded everywhere by granular protoplasm, and in this protoplasm the nuclei are now very numerous. The axis cylinder cannot be distinguished in the mass, as a rule, but occasionally a fine line is seen passing through the mass, which may be a remaining cylinder. The succeeding stage presents a different picture. While up to this time the size of the nerve-fibre has remained about normal and uniform, it is now seen to vary. At places the fibre is still wide and filled with a granular mass, at other places it is narrow, the mass having disappeared, leaving either a collapsed sheath, or a sheath containing only nuclei here and there. In a few such narrow fibres there seems to be an axis cylinder lying directly within the sheath of Schwann, and occasionally separated from it at various places by nuclei. But this appearance is rarely seen. As a rule, no trace of the axis cylinder remains. As any single fibre may show at some places constrictions, at other dilatations, the variations in its calibre is the most striking feature of this stage. In the terminal stage the calibre is uniform again, but is now everywhere reduced. The sheath of Schwann is empty, or contains only a little granular substance, and the nuclei are now less numerous than before. There is in fact only an atrophied tube with none of its original contents. These tubes lying side by side are folded and undulating, and appear like a strand of connective tissue.

These various stages of parenchymatous inflammation are to be seen in different fibres in the same specimen. Their appearance is identical with that observed in the course of degeneration of a nerve after compression, or after destruction of the spinal ganglion-cells. This has led such an accurate observer as Erb to advance the hypothesis that some slight changes in trophic cells in the spinal cord, not visible to the microscope, are present primarily, and that these changes are of a secondary nature. But this cannot be admitted.

It cannot but be admitted that the first class of cases of neuritis must be considered as due to a primary parenchymatous inflammation in the nerve-fibres. This form seems to be much more frequent in its occurrence than the first variety, and constitutes the lesion in the majority of the cases hitherto reported.

A second class of cases presents a different appearance.

In this class the mere inspection shows the nerve to have been the seat of pathological changes, for it is either congested, swollen, and lacking in lustre, or it is yellow and irregularly swelled by the accumulation of fat, or it is evidently reduced to a mere connective-tissue strand. Upon teasing the nerve it is at once clear, from its brittleness, that individual fibres are lacking in continuity and are changed in structure. And if it is examined under the microscope, the exudation of serum, and of lymphoid bodies, the great increase in the number of connective-tissue nuclei, the distended condition of the vessels, as well as the various appearances characteristic of nerve degeneration,

<sup>10</sup> Loc. cit., II., 42-47.

are clearly seen. Here the inflammation is either originally an interstitial inflammation or, more probably, a diffuse one. It is possibly that the degenerative processes in the nerves may have been due to the compression by the exuded products of inflammation within the nerve-sheath. . . .

It is to be noted that in both of these forms the pathological changes are always more intense in, and are occasionally limited to, the peripheral terminations of the nerves. The nerve-trunks may be slightly involved in their distal portions, but it is very rare to find any changes in them at their origin from the plexuses. And, as a rule, the spinal nerve-roots in cases of multiple neuritis are normal. In making autopsies upon such cases this fact is to be remembered, and the nerves are to be removed down to their finer branches in the muscles and fascia.

One additional pathological form must be mentioned, since it has been described by such a careful observer as Gombault.<sup>11</sup> It is the so-called segmental periaxillary neuritis. In toxic neuritis from lead poisoning, Gombault found that the degenerative process was not uniform in the entire length of a nerve-fibre. On the contrary, entirely normal segments alternated with the degenerated segments in the nerves. . . .

While it is, of course, impossible to describe definitely, the process which goes on to complete regeneration of nerves in multiple neuritis, there is no reason to suppose that it differs in any way from that observed in experimental lesions.

The time required for the completion of the process will depend upon the severity and extent of the degeneration. When that is slight the recovery may be rapid, cases having been reported where a total cure took place in two months. As a rule, however, it is a slow process. The large majority of the cases on record required over four months for the complete regeneration, and is not a few cases from ten to sixteen months elapsed before the condition of the nerves was proved to be normal by the total disappearance of all symptoms.

With the end of 1883 we may consider the third stage of pathological discovery in the history of multiple neuritis as terminating. At that date the symptoms of the disease had been recognized as constituting a distinct clinical picture; hypothetical lesions in the spinal cord had been abandoned, and the exact pathology of the disease had been ascertained. Since 1883 the final period in the development of knowledge of the affection has been in progress.

About one hundred cases, of varying degrees of severity, have been observed (see Bibliography). The lesions described have been confirmed in all their details. The symptoms arising in the course of the disease have been subjected to careful analysis, together with their varied modes of combination. Certain diseases hitherto considered of spinal origin are found to be due to peripheral disease. Thus it has been discovered that a form of ataxia may occur from multiple neuritis of alcoholic or arsenical poisoning, which closely resembles and was formerly confounded with tabes; also, that some cases supposed to be anterior poliomyelitis must now be differently named. And as physicians review their records, they find that former diagnoses require revision in the light of new discoveries, and that greater circumspection is to be

exercised in differentiating spinal from peripheral affections. The grounds for such differential diagnosis will require attention in the next lecture. And, what is perhaps of greater importance, the fact has been elicited that some combinations of symptoms formerly supposed to be without a pathological basis, some of the so-called peripheral neuroses, really belong to this class of diseases. At present we have only time to allude to one or two forms of peripheral neuroses, which must be removed from that unsatisfactory category of disease and be considered as peripheral neuritis.

And the first of these is the affection termed numb-fingers. This was first described by J. J. Putnam, of Boston, but met with instant recognition from neurologists and from general practitioners all over the world. It is a disease chiefly seen in women between the ages of forty and sixty, usually associated with dyspeptic or uterine symptoms, but entirely independent of them. It begins as a tingling sensation in the ends of the fingers, felt at night, and sufficiently annoying to keep the patient awake. It then extends to the entire fingers, and may invade the hand, and is felt by day as well as by night. The fingers are so numb that all finer acts become impossible; the patient can no longer sew or knit, cannot be sure of holding anything securely, and finds herself unable to perform any delicate movement. Sometimes a slight degree of anæsthesia and analgesia can be discovered by ordinary tests, but often the disturbance of sensation is purely subjective. There is rarely any incoördination, and paresis is usually wanting. It may develop in the feet as well as in the hands, making walking more or less disagreeable, and adding to the discomfort of the patient. The affection is of indefinite duration, often subsiding quickly under treatment, sometimes baffling all attempts to arrest it. For a time it was considered a purely functional affection, then a spinal-cord disease, but now, in the light of the parallelism between the symptoms mentioned and those which are characteristic of multiple neuritis, we cannot but consider it a slight form of this disease.

The second of the peripheral neurosis which must be referred to peripheral neuritis is intermittent paralysis. Cases of sudden paraplegia, lasting a few hours and passing off as rapidly as it appeared, have been observed too frequently to admit of any doubt. Westphal has described such a case in which no cause could be found. Gibney reported some cases presumably due to malaria. Others have thought the disease of functional character, either central or peripheral. But in the light of recent observations upon infectious cases of multiple neuritis it becomes evident that these sudden, transient paraplegias find their adequate explanation in such an affection.

And, lastly, there are numerous cases of indefinite nervous symptoms, pain of various kinds, formication, and odd sensations grouped under the indefinite term numbness, flashes of cold and heat accompanied by actual changes in the temperature of the part, or only by apparent vascular irregularities, slight spasms, or tremors; functional weakness, with sense of fatigue not reaching the grade of paresis, and many equally obscure manifestations of disturbed function in various parts of the body, which reach their best explanation in the theory of multiple neuritis.

And since it was one of the objects of the founder of this lectureship to determine the true nature of such

<sup>11</sup> Gombault. *Archives de Phys.*, 1873, p. 592; also *Arch. de Neurol.*, 1, 1.

peripheral neuroses, it is with the greater interest that we examine the disease to which they must be assigned.

In the present stage of progress in the history of neuritis much attention is being given to the etiology of the disease. Cases which, from their causation, were formerly separated, are now found to be closely allied in their pathology. Thus the forms of paralysis occurring after the ingestion of various poisons, such as arsenic, lead and alcohol, are known to be due to a common pathological change. The various kinds of sensory and motor disturbance occurring as complications of the acute diseases, diphtheria, variola, typhoid and typhus fevers, and severe malarial fever, are traced to a lesion in the peripheral nerves. Tuberculosis is known to predispose to neuritis, and many cases formerly supposed, without question, to be produced by central or meningeal affections of a tubercular character, are now assigned to a peripheral cause. It is a question whether syphilis will cause a simple degenerative neuritis, but syphilitic affections of the nerves are easily recognized and well known. Nor can the nervous system escape the action of those micro-organisms which are now recognized as the constant cause of many diseases. There is an epidemic form of multiple neuritis, fortunately not prevalent in this country, but occasionally imported here in the form of sporadic cases, known as kakke, or beriberi, the bacillus of which has recently been discovered and cultivated. And, lastly, there is a class of cases, of supposed spontaneous origin, in which cold or overexertion are assigned as causes, but which need further investigation in regard to their etiology.

It is evident from this array of causes that several conditions, formerly separated from one another because of the different circumstances of their occurrence, are really forms of the same disease. But while they may be brought together upon a pathological basis, and while all have many symptoms in common, each of the forms of neuritis presents certain distinct features.

### THOUGHT-TRANFERENCE.<sup>1</sup>

BY MORTON PRINCE, M.D.,

Physician for Nervous Diseases, Out-Patient Department, Boston City Hospital.

I HAVE been asked, for the benefit of those who have not followed the experimental investigations in thought-transference, and in view of the present popular interest taken in professional "mind-reading," so-called, to give an account, to-night, of the work that has been done in the investigation of these phenomena, and of the results thus far reached. I cannot, therefore, do much more than give a general *résumé* of the subject, as it now stands.

The experimental investigation of mind-reading, which was first systematically carried out in England, grew out of the popular interest taken in the well-known "willing game." The principle of this game is that one or more people will that another person shall do something — such as touch some object in the room, or take something from a given place, and put it in another place.

The willers are usually in contact or in close

contiguity to the one who is willed. It is well known that most of these performances are done by voluntary or involuntary pushing on the part of the willers. Still there remains over a small residue of phenomena, which it was thought seemed to point to something more, and to be sufficiently well attested and important to become the legitimate object of serious scientific investigation. Accordingly, in the early part of 1882, a number of gentlemen well known in England for their scientific, literary, and other attainments, formed the society known as that for Psychical Research. Its object was to provide a machinery and means for the systematic study into all such phenomena as are commonly designated by the terms, mesmeric, psychical, spiritualistic, etc.

The subject of mind-reading, afterwards called thought-transference, was given to such men amongst others, as Prof. W. F. Barrett, Edmund Gurney, F. W. H. Myers, Prof. Balfour Stewart, and Prof. Alfred Hopkinson. It will thus be seen, at the outset, that the work has not been undertaken by a lot of irresponsible and uncultured impressionists, but by men of unquestioned intellectual capacity and integrity.

By mind-reading is meant the power of one person directly inducing an idea, similar to his own, in the mind of another person, without conveying any information through any one of the five senses. This definition, it will be observed, makes the person whose mind is read the *active* agent, while the mind-reader, the one who becomes conscious of the other's thoughts, is the *passive* agent. This is the more correct interpretation of the phenomena than the usual inverse definition, as it emphasizes the active and essential part played by the person whose thoughts are transferred — a point often lost sight of.

It appears that previous to the experiments undertaken by the Society, the attention of a Rev. Mr. A. M. Creery, B.A., having also been called to the phenomena of the well-known "willing game," he determined to investigate it, with the idea of ascertaining whether any of the results were due to the simple action of willing, as well as to involuntary pushing. "For this purpose," to use his own words, "I employed four of my children, between the ages of ten and sixteen, all being in perfectly robust health, and a maid-servant about twenty years of age. Each went out of the room in turn, while I and the others fixed on some object, which the absent one was to name on returning to the room. After a few trials, the successes preponderated so much over the failures, that we were all convinced there was something very wonderful coming under our notice. Night after night, for several months, we spent an hour or two each evening in varying the conditions of the experiments, and choosing new subjects for thought-transference.

"We began by selecting the simplest objects in the room; then chose names of towns, names of people, dates, cards out of a pack, lines from different poems, etc.; in fact, any thing or series of ideas that those present could keep steadily before their minds; and when the children were in good humor, and excited by the wonderful nature of their successful guessing, they very seldom made a mistake. I have seen seventeen cards, chosen by myself, named right in succession, without any mistake. We soon found that a great deal depended on the steadiness with which the ideas were kept before the minds of 'the thinkers,'

<sup>1</sup> Read before the Section for Clinical Medicine, Pathology and Hygiene, of the Suffolk District Medical Society, December 8, 1886.

and upon the energy with which they willed the ideas to pass. . . .

"The distance between the thinkers and the thought-readers is of considerable consequence. As a rule, the best results take place when this distance is not more than a yard or two; but under very favorable mental conditions, we have often had four or five cards named right in succession, while the thought-reader was placed in a room on the landing above that in which the thinkers were assembled."

So far, however extraordinary the phenomena appeared to be, they were of course of no value as evidence, on account of the want of rigor in the conditions under which the experiments were performed. Mr. Creery, however, communicated the facts to Professor Barrett, who under more stringent conditions repeated the experiments. Later they were further investigated by Mr. and Mrs. Sedgwick, Prof. Balfour Stuart, Prof. Alfred Hopkinson, and the committee on thought-transference. A large number of experiments were performed, while every possible precaution, which the committee could devise, was taken to prevent any information being acquired by the subjects through any one of the senses, including under this, of course, collusion. It will be impossible for me, this evening, even if desirable, to describe with any diffuseness the large number of experiments that have been made, and shall limit myself to a general description of the methods employed, and a few examples of the results arrived at. It should be stated, as bearing to a limited extent on the question of intentional fraud that Mr. Creery is vouched for as a man "of unblemished character, and whose integrity indeed has, it so happens, been exceptionally tested." This would not however bear upon the question of intentional deception on the part of the children.

The method pursued in the inquiries were as follows:

The places where the experiments were performed varied; sometimes being at the house of Mr. Creery, sometimes in other rooms chosen by the experimenters. The usual practice was to send a child out of the room. The name of an object, such as a penknife, box of chocolate, or a number, or a playing-card drawn at random from a pack, or a *fictitious* name was written upon a piece of paper and silently shown to those present. The child was then recalled, by one of the experimenters. From this time not a word was allowed to be spoken, save "Right" and "No" in response to the guesses of the child, who stood near the door with downcast eyes. No one was allowed to enter or leave the room. No other sound, than the above responses or movements by any one, were permitted. Sometimes the rest of the family remained in the room and sometimes they were excluded; sometimes they were shown the name of the thing to be guessed and sometimes not. The results by this did not appear to be essentially altered in either case. As an example the following may be cited.

Easter, 1881, present: Mr. and Mrs. Creery and family, and W. F. Barrett, the narrator. "One of the children was sent into an adjoining room, the door of which I saw was closed. On returning to the sitting-room and closing the door also, I thought of some object in the house, fixed upon at random; writing the name down, I showed it to the family present, the strictest silence being preserved throughout. We then

all silently thought of the name of the thing selected. In a few seconds the door of the adjoining room was heard to open, and after a very short interval the child would enter the sitting-room, generally speaking with the object selected. No one was allowed to leave the sitting-room after the object had been fixed upon; no communication with the child was conceivable as her place was often changed. Further, the only instructions given to the child were to fetch some object in the house that I would fix upon, and together with the family, silently keep in mind to the exclusion, as far as possible, of all other ideas. In this way I wrote down, among other things, a *hair-brush* (It was brought); an *orange* (It was brought); a *wine-glass* (It was brought); an *apple* (It was brought); a *toasting-fork* (Failed on the first attempt, a pair of tongs being brought, but on a second trial it was brought). With another child, (among other trials not here mentioned), a *cup* was written down by me (It was brought); a *saucer* (This was a failure, a plate being brought; no second trial allowed. The child being told it was a saucer, replied, 'That came into my head; but I hesitated, as I thought it unlikely you would name saucer after cup, as being too easy'.")

#### EXPERIMENTS MADE APRIL 13TH, 1882.

##### Objects to be Named.

A white penknife.—Correctly named, with the color, the first trial.

Box of almonds.—Correctly named.

Threepennypiece.—Failed.

Box of chocolate.—Button-box said; no second trial given.

Penknife hidden.—Failed to name the place.

##### Numbers to be Named.

Five.—Correctly given the first trial.

Fourteen.—Failed.

Thirty-three.—54 (No), 34 (No), 33 (Right).

Sixty-eight.—58 (No), 57 (No), 78 (No).

##### Fictitious Names to be Guessed.

Martha Billings.—Failed; Biggis was said.

Catherine Smith.—Catherine Shaw was said.

Henry Cowper.—Failed.

##### Cards to be Named.

Two of clubs.—Right first time.

Queen of diamonds.—Right first time.

Four of spades.—Failed.

Four of hearts.—Right first time.

King of hearts.—Right first time.

Two of diamonds.—Right first time.

Ace of hearts.—Right first time.

Nine of spades.—Right first time.

Five of diamonds.—Four of diamonds (No), four of hearts (No),

five of diamonds (Right).

Two of spades.—Right first time.

Eight of diamonds.—Ace of diamonds said; no second trial given.

Three of hearts.—Right first time.

Five of clubs.—Failed.

Ace of spades.—Failed.

As comments on these experiments the committee

remarks:

"Now if we apply to these two sets of experiments the sources of error enumerated by Dr. Beard, the conclusion, we venture to think, is inevitable that we have here very strong evidence in favor of a class of phenomena entirely new to science. Involuntary actions, such as movements of the lips, etc., could not reach the child when she was out of sight and hearing, as was the case in the first series of experiments. *Conscious or unconscious deception* on the part of the subject does not apply, as the thing wished for was selected and written down by one of us. *Collusion* by a third party is avoided by the fact that none were allowed to enter or leave the room until we had selected the thing to be guessed and in the second series of experiments

riments by the exclusion of all members of the family either from the room or from participation in the requisite knowledge; whilst *chance* and *coincidence* we have already dealt with. In many trials, such as the guessing of fictitious names, made up by us on the spur of the moment, the chances against success were, of course, incalculable; yet, as will be seen by the following record taken from our last day's experimenting, these names were guessed with as much ease as cards, where the chances against success were far less."

Among the experiments selected April 17th, 1882, was the guessing of fictitious names. The results were as follows:

Words chosen.	Words guessed.
William Stubbs.	William Stubbs.
Eliza Holmes.	Eliza H—
Isaac Harding.	Isaac Harding.
Sophia Shaw.	Sophia Shaw.
Hester Willis.	Canandra, then Hester Wilson.
John Jones.	John Jones.
Timothy Taylor.	Tom, then Timothy Taylor.
Esther Ogle.	Esther Ogle.
Arthur Higgins.	Arthur Higgins.
Alfred Henderson.	Alfred Henderson.
Amy Frogmore.	Amy Freemore, then Amy Frogmore.
Albert Snelgrove.	Albert Singrore, then Albert Grover.

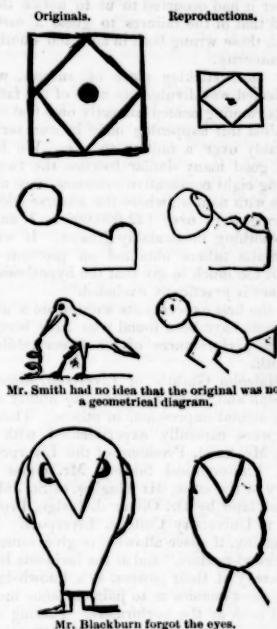

After this, a Mr. Smith of Brighton was found, who in conjunction with Mr. Blackburn, a member of the society, was able to do what had been done by the Creery children. In addition, however, it was found that Mr. Smith was able to reproduce drawings of mental pictures in the mind of Mr. Blackburn. In the earlier experiments of this kind, Mr. Smith held Blackburn's hand for a few moments, and then releasing it while still blindfolded, drew his own impression of the figure. The original, of course, had been previously determined and drawn by the committee and shown by them to Blackburn. Later the conditions were made still more stringent, no contact at all being allowed. The *modus operandi* is described as follows: (162)

"The percipient, Mr. Smith, is seated blindfolded at a table in our own room; a paper and pencil are within his reach, and a member of the committee is seated by his side. Another member of the committee leaves the room, and outside the closed door draws some figure at random. Mr. Blackburn, who so far has remained in the room with Mr. Smith, is now called out, and the door closed; the drawing is then held before him for a few seconds, till its impression is stamped upon his mind. Then, closing his eyes, Mr. Blackburn is lead back into the room and placed standing or sitting behind Mr. Smith at a distance of some two feet from him. A brief period of intense mental concentration on Mr. Blackburn's part now follows. Presently, Mr. Smith takes up the pencil amidst the unbroken and absolute silence of all present and attempts to reproduce on paper the impression he has gained. He is allowed to do as he pleases as regards the bandage round his eyes; sometimes he pulls it down before he begins to draw, but if the figures be not distinctly present to his mind, he prefers to let it remain on, and draws fragments of the figure as they are perceived. During all this time, Mr. Blackburn's eyes are generally firmly closed (sometimes he requests us to bandage his eyes tightly as an aid to concentration), and except when it is distinctly recorded he has not touched Mr. Smith, and has not gone in front of

him, or in any way within his possible field of vision since he re-entered the room.

"When Mr. Smith has drawn what he can, the original drawing, which has so far remained outside the room, is brought in, and compared with the reproduction. Both are marked by the committee and put away in a secure place. The drawings and reproductions, given at the end of the Report are in every case fac-similes of the untouched originals, from which they have been photographed on the wood blocks."

A few examples of these drawings with the reproductions I have attempted to reproduce here. [A number of diagrams were shown the audience a few of which are printed here.]

In order to determine whether the results thus far reached might be attributed to chance, they were submitted to mathematical calculation. The results thus calculated have been arranged in tabular form, I have had them copied here upon this blackboard. You will see that the probabilities are immensely against the results being due to blind chance and in favor of there being some other active agent. In some cases you will see that the probabilities against chance are almost infinite. Referring to this, the Committee made the following comments:

"The outline of results during the present investigation, which extended over six days, stands as follows: Altogether 382 trials were made. In the case of letters of the alphabet, of cards, and of numbers of two figures, the chances against success on a first trial would be naturally 25 to 1, 51 to 1, and 89 to 1, re-

spectively; in the case of surnames they would, of course, be indefinitely greater. Cards were far most frequently employed, and the odds in their case may be taken as a fair medium sample; according to which out of the whole series of 382 trials, the average number of successes at the first attempt by an ordinary guesser would be  $7\frac{1}{2}$ . Of our trials 127 were successes on the first attempt, 56 on the second, 19 on the third, making 202 in all. On most of the occasions of failure, 180 in number, second trials were made; but in some cases the guesser professed inability, and declined to make more than one, and in others we allowed three; no trial beyond the third was ever allowed. During the last day or two of trial, after it had occurred to us to notice the point, we found that of the failures to guess a card at the first trial, those wrong both in suit and number were a small minority.

"Our most striking piece of success, when the thing selected was divulged to none of the family, was five cards running named correctly on a first trial; the odds against this happening once in our series were considerably over a million to one. We had altogether a good many similar batches, the two longest runs being eight consecutive successes, once with cards and once with names; where the adverse odds in the former case were over 142,000,000 to 1, and in the latter something incalculably greater. If we add to these results others obtained on previous visits, it seems not too much to say that the hypothesis of mere coincidence is practically excluded."

Since the first experiments were made a number of other people have been found who have been able to repeat the performances of the Creery children and Mr. Smith.

Mr. Malcolm Guthrie, of Liverpool, discovered in Miss Relp and Miss Edwards the ability to reproduce the mental impressions of others. These young women were carefully experimented with by Mr. Guthrie, Mr. Steel, President of the Liverpool Literary and Philosophical Society, Mr. James Birchall, Secretary of the same, Mr. Hughes, of St. John's College, and later by Dr. Oliver J. Lodge, Professor of Physics in University College, Liverpool. It would be interesting, if space allowed, to give some account of the "mind-readers," and of the incidents leading to the discovery of their powers, as a knowledge of the circumstances enables us to judge in some measure of the good faith of the performers. Passing over this I can only say that the experimenters apparently, judging by the published reports, took every conceivable precaution to guard against fraud, and unconscious deception.

The fact here should not be allowed to escape notice, that here we have to do with an entirely different and independent set of experimenters, as well as performers. The chances that there were sources of fallacies which escaped the first experimenters are lessened by their being undetected by a second independent set of observers.

The following gives an idea of the results obtained with guessing objects. The conditions of the experiments as described were generally very stringent, and in the ones here quoted no contact was allowed. They include all the experiments made on the particular date given, April 9th, 1883. Present: Mr. Guthrie, Mr. Birchall, Miss R., Miss R—d, Miss J., Miss E., and Miss C. Percipient, Miss R.

## Objects.

## Answers.

- A gold cross.—It is yellow. . . it is a cross.  
A red-ivory chess knight.—It is red . . . broad at the bottom . . . then very narrow . . . then broad again at the top. It is a chessman. Asked to name the piece, said she did not know the names of the pieces.  
A half-crown.—It is round . . . bright . . . no particular color. . . silver . . . it is a piece of money . . . larger than a shilling but not as large as . . . The percipient was unable to say more.  
A diamond of pink silk on black satin.—Light pink . . . cannot make out the shape . . . seems moving about. N.B.—The object was held somewhat unsteadily by Mr. G.

As it is the successes that are of particular interest, I have selected the following from a large number of trials at different sittings.

## Objects.

## Answers.

- An egg.—Right.  
A penholder with thimble inverted on the end.—A column, with something bell-shaped.  
A small gold earloop.—Round and bright . . . round and bright . . . with loop to hang it by.  
A gilt cross.—Right.  
A yellow paper-knife.—Yellow. . . Is it a feather? It looks more like a knife with a thin handle.  
A pair of scissors standing open and upright.—Is it silver. . . No—it is steel. . . It is a pair of scissors standing upright.  
A diamond of blue silk on black satin.—It is a diamond.  
An apple.—Right.  
An orange.—Right.  
Letters G. D. V.—Right.  
A key first looked at and then withdrawn and thought of only.—Right.  
A plain gold cross, imagined only, not seen.—Right.  
Mr. J's. gold chain and pendant, imagined only.—Right.  
A pineapple, imagined only.—Right.  
Letter C.—Right.

These are but samples of the results of a large number of experiments which were continued on a number of occasions. Of course there were a considerable number of failures; on the other hand, some of the successes were very brilliant. A number of experiments were also made in reproducing drawings after the manner of Mr. Smith, these were very successful. A few of these, perhaps the most striking, are reproduced here that a better idea may be obtained of the degree of success attained.

Experiments were also made in the reproduction of the sensations of *taste*, *smell*, and *pain*, with equally successful results.

It is proper to state, as it bears on the responsibility and good faith of the experimenter, that Mr. Malcolm

Originals.

Reproductions.

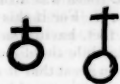

Mr. Guthrie and Miss E. No contact.

Mr. Hughes and Miss E. No contact. Miss E. said, "It is like a mask at a pantomime," and immediately drew as above.

Original at left.

Original at top.

Mr. Guthrie and Miss E. No contact. Miss E. almost directly said, "Are you thinking of the bottom of the sea, with shells and fishes?" and then, "Is it a small or a fish?" — then drew as above.

Guthrie is represented as holding "an important position in Liverpool, being a Justice of the Peace, and an active member of the governing bodies of several public institutions, among others of the new University College; that he is a severe student of philosophy, and the author of several works bearing on the particular doctrines of Mr. Herbert Spencer." At the request of Mr. Guthrie, Professor Oliver J. Lodge, D.Sc., later took part in the experiments, superintending the conditions and modifying the details. In his reports he confirms all the previous results.

Since this a number of people in different parts of England have given accounts of similar experiences and claimed for them evidence of true thought-transference. But the testimony in these cases is not sufficiently full or well attested to give the experiments the same weight that may be given to those just discussed.

Such are the facts which we have to consider. Then remains the question, "What conclusions do they admit of?" What interpretation is to be put upon them. The distinction between the facts and the interpretation of those facts cannot be too strongly emphasized. We cannot be too often reminded of this distinction; it must constantly be borne in mind. Admitting the results thus far obtained to be true, does it necessarily follow that the explanation is to be found in a direct transference of thought? Is there any other explanation possible; and is it not logical to admit the facts and deny the conclusions? Let us review the evidence as it at present stands:

*First.* We have as experimenters a number of gentlemen noted for their integrity, and whose standing would exclude all intention at deceit on their own part.

*Second.* The experimenters, after considerable previous experience, arrange the conditions of the experiments, so as to exclude by every possible device all possibility of communication by the ordinary channels, the senses (including collusion.) They are allowed to arrange the conditions according to their own option, in such a way as to test in the most stringent manner the phenomena under investigation. In this way the experiments differ essentially from those made with ordinary professional spiritualists and mind-readers. Under those stringent conditions, results are obtained showing that the thoughts of one mind have been communicated in some way to another.

*Third.* The experimenters conclude that the communication has been made by direct thought-transference.

Regarding the second count, the evidence to most people, at any rate, to such as have studied the reports of the investigations thus far made, will seem overwhelmingly in favor of the accuracy of the alleged facts; but it may be logically urged that opinions founded from *reported accounts* of experiments are of little value; the more faultless the report, the more certain that opinions founded on it are but the repeti-

tion or reflex of the opinions of the original experimenters, which alone are of value. Opinions founded on it are like soldiers in a theatre, who, being made to go round in a circle, appear to be many-fold more numerous and effective than they are.

It is only the opinions of the experimenters themselves which are of value. Thus far, the number of subjects who have given successful results have been comparatively small, and the observers likewise limited. However accurate the latter may be, a person cannot be accused of extreme skepticism who should urge, in view of the extreme rarity of a keenness of intellect requisite for accurate observation, as well as the unfamiliar nature of the phenomena, that the observers may have overlooked sources of fallacies that may yet appear; and it is only by multiplying the observers, as well as the subjects, that the phenomena themselves can be established beyond possibility of doubt.

Regarding the third count, the conclusions of the Committee, it may be said in their favor that there is no inherent improbability against them. We know that nerve-force, in many ways, manifests properties similar to those of electrical-force. We know that if a current of electricity be passed through a wire in the neighborhood of another closed circuit of wire, the first current will *induce* a second current in the second wire. Now there is no reason why, in a similar way, the neural currents of the brain should not *induce* similar currents in homologous centres in a neighboring brain under favorable conditions. To some minds, indeed, it may seem strange if they didn't.

Similar analogies may be found in a magnet being affected by neighboring iron or another magnet; in the sun's action upon the earth; and in a globe set into vibration by the vibrations of another globe.

In the second place, admitting the phenomena, it may be said that, in the absence of all communication by the senses, direct thought-transference is the most rational and obvious explanation. But, on the other hand, it may be urged that this explanation seems more obvious merely because of the limitation of our knowledge, and that if we had a more intimate acquaintance with psychical phenomena, we might find other as yet unknown channels by which information might be unconsciously conveyed from one mind to another; or that an explanation might be found in laws of thought by which two minds, under similar conditions, should pursue the same course. At any rate, this last possibility has not as yet been sufficiently worked out.

If called upon to summarize the evidence as it stands, I should say that: *First*, all the evidence that we possess, such as it is, goes to prove that certain persons, under certain favorable conditions, can become cognisant of the thoughts of another without any communication by the senses. *Second*, that the best *working* hypothesis that we possess is in favor of direct thought-transference as an explanation. *Third*, *à priori*, there is nothing inherently impossible or improbable in the hypothesis. *Fourth*, the subject must be considered as still *subjudice*, and needs further investigation to settle the question beyond possibility of doubt.

Before dismissing the subject, I wish to say a few words in regard to the nature of the evidence before us: There are two objections or arguments which are commonly employed against thought-transference: One is that similar claims have been made almost

from time immemorial by spiritualists, clairvoyants, and the like; that all sorts of equally extraordinary performances have been done by these sort of people; but as each has been investigated, it has broken down and failed to stand the tests of rigid examination; or if not, that no thorough examination has been allowed. Furthermore, the performances of professional jugglers, like Herman and Heller, are cited as evidence, showing how easy it is to impose upon even the clearest observer.

To my mind, objections of this sort are most illogical and unscientific. There is not the slightest parallel between the two cases. In the first place, no one can find the slightest similarity between professional mediums and the earnest, conscientious, responsible people who have conducted the investigations, many of them skilled by profession in experimental methods of research; nor even between the former and the "mind-readers," like the Liverpool young ladies, Miss R. and Miss E., and the Creery children.

In the second place, no physical experiments in the laboratory have been more under the control of the chemist and the physiologist than have these. The subjects have given themselves up to the experimenters, not occasionally and fitfully, but day after day. Any and every sort of condition have been cheerfully acquiesced in and imposed. They have seemed, judging by the reports, to take the same interest in studying the question as any one else. Nor are the conditions of the experiment apparently complex. It seems as if the only essential conditions requisite are to see that the subject or percipient does not get any clue to the agent's thought through any one of the five senses—touch, taste, smell, sight, and hearing.

The first three are easily excluded. It would seem as if the latter two could easily be. No paraphernalia are used; no dark closets, no strange rooms; no attempt to regulate the experiment. The subjects, too, in no case have been trained professionals, and, in one case, only children. It seems strange, at first sight, that so many adult intelligences could be deceived under such conditions by such youthful minds. The experiments, too, have not been carried out by one set of people only; on the contrary, the same subjects and different subjects have been examined by independent observers, and each has confirmed the results previously obtained.

The second objection, referred to as usually raised, is that the existence of thought-transference is so inherently improbable that the chances are far greater that there has been some error in the observations than that the hypothesis is true. This objection, in the first place, overlooks the distinction between the facts and the interpretation of the facts which I have already insisted upon. Further, in my judgment, it seems to me far from the truth. Whether I admit thought-transference or not, I see no valid ground on which to base such an assumption nor, so far as I know, has any been given. If thought-transference directly contradicts some well-established law, as perpetual motion would that of gravitation, then it might be said that it was inherently improbable. But no established fact or law is controverted by it. If, again, the theory of thought-transference maintained that there was a constant influence of one mind upon another or others, that all minds act and interact upon one another in the course of the ordinary affairs of life, or that complicated processes of thought

were transferred from one individual to another, then it might with reason be said that there was an inherent improbability against the theory. For if this were the case, the probability of the fact, having so long escaped detection, would be small, while the disastrous consequences to society would be so great that it might be doubted whether progress in civilization could go on.

But the theory is far less extensive than this. The conditions under which thought-transference can take place, if at all, are very limited, while the ideas themselves are very simple. The number of people, too, who possess the alleged faculty is comparatively very small. It is necessary that the agent, who is as essential for success as the percipient, shall concentrate his attention, to the exclusion of all other thoughts, on a particular idea. If he cannot do this, the experiment will probably fail. The percipient must likewise put himself into a state which may be called expectant attention, excluding as far as possible all consciousness of surroundings. The idea to be transferred must be simple, such as a mental picture of an object, not too complicated in structure, a number, a taste, or a pain. The more complicated the idea the greater the liability of failure, complete or partial. It seems to me that one of the strongest points in favor of the theory is the failures themselves. They are just what would be expected under the theory. A careful analysis of the failures will show, I think, that their character comports exactly with what would be predicted from the theory itself. Space and time will not allow me to go into this here. But, in conclusion, we may say the experiments furnish two classes of facts, namely, successes and failures, both of which furnish strong affirmative evidence for the theory. But still in spite of this strong presumptive evidence, it is given by too few experimentally, and the subjects have been too sparse to justify us in accepting the hypothesis without further confirmation.

It may not be out of place before concluding, to caution you not to confuse these phenomena with those of muscle-reading as performed by so-called professional mind-readers. The latter class of experiments have of late been so exhaustively discussed that it is not worth while to more extensively refer to them here. Those who are interested will find in the *Nineteenth Century* for December, 1886, a very entertaining article by Mr. Stuart Cumberland, a very successful professional, who has retired from the business. He now furnishes the public with a very complete explanation of how the tricks are done.

## RECENT PROGRESS IN LEGAL MEDICINE.

BY F. W. DRAFER, M.D.

### WOUNDS OF THE GENITAL ORGANS IN THEIR RELATION TO CRIMINAL ABORTION.

LESSER<sup>1</sup> has observed eleven cases of wounds of the uterus or vagina, produced by instruments used to induce abortion. In these eleven cases, there were thirty-eight lesions, as follows: eight wounds of the vagina, twenty of the cervix, or of the body of the womb adjacent to the cervix, ten of the remainder of the uterine body. In German and other medical literature of the last twenty years, Lesser found mention of twenty-eight additional cases, in which the lesions involved the vagina seven times, the cervix and lower

<sup>1</sup> Vierteljahrschrift f. gerichtl. Med. N. F. xlv, page 1.

zone of the uterine body nine times and the rest of the body of the womb twelve times.

The wounds observed by Lesser were lacerations or punctures except in four instances of contusions of the vagina and cervical mucosa. He raises the question whether the expulsion of the fœtus is expedited to a greater degree when the wounds involve the body of the womb than when they affect the cervix and vagina only. His notes in eleven cases favorable for a determination of the question show that neither the seat nor the extent of the injuries has any constant relation with the rapidity of the abortion or with the energy and frequency of the uterine contractions. The interval between the operation for the abortion and the expulsion of the fœtus was eight hours in one case, where punctures and contusions were found in the upper part of the body of the womb; twelve to sixteen hours with a perforating wound near the fundus of the organ; twenty-four hours with a wound of the posterior wall of the body of the womb; twenty-four to forty-eight hours with another wound of the body. In the cases of cervical lesions only, the interval was from one to nineteen days; where the vagina alone was involved, the period of delay varied from two to five days.

Lesser remarks that the rapidity of the abortion is especially controlled by a perforating puncture of the ovum and by the extent to which the membranes are torn; and that the lesions of the womb or vagina which do not involve the uterine contents doubtless play a secondary part only. He mentions the case of a multipara who at about the fourth month of her pregnancy submitted herself to an operation for an abortion which produced a deep punctured wound of the cervix; the fœtus was not expelled till the nineteenth day, although there had been from the sixth day inflammation of the external genitals, with swelling and tenderness of the abdomen and other signs of peritonitis.

Lesser declares, also, that the presence and the extent of wounds have no influence upon the interval between the operation and the death when the abortive procedures result fatally. In the cases of wounds of the womb, he notes the death as occurring four, seven, nine, twelve, thirteen, nineteen and twenty-two days and, in one case, more than a month, after the operation; while in cases where no traumatism was produced, the death followed on the sixth, ninth, twelfth, thirteenth, twenty-seventh and thirty-first day. These two series of cases are regarded as properly comparable, because the cause of death is invariably puerperal fever.

#### WATER IN THE STOMACH AS A SIGN OF SUBMERSION DURING LIFE.<sup>2</sup>

A man's dead body was found in a ditch and it was suspected that the death was due to criminal violence. The autopsy disclosed the following, among other appearances: a contusion in the left temporal region; another contusion on the right cheek; three short excoriations on the left side of the neck and two on the right, between the larynx and the sterno-mastoid muscle, with extravasation of blood beneath them; the lungs fully distended, emphysematous, of purple color, with deep-seated hæmorrhages of considerable size, but without water or froth in the air-passages

and without injection of the mucous membrane; the right cavities of the heart distended with dark, liquid blood, and the liver likewise engorged. The stomach was filled with food floating in a quantity (from 300 to 400 grammes) of turbid fluid without any odor of alcohol, or beer, or coffee. Among the negative data noted were the absence of froth from the nostrils and mouth, the unsodden state of the hands, the normal appearance of the eyes, the natural position of the tongue, and the unaltered condition of the brain and spinal cord. The inspector, Dr. Duriau, formulated his opinion that the deceased came to his death by manual strangulation, after an unsuccessful attempt to destroy him by submersion. There were, he believed, sufficient evidences of the asphyxia by strangulation; there was room for question relating to the attempt at murder by drowning. The air-passages did not present a trace of froth, a sign which is justly regarded as of the highest value. The body had been in the water only seven hours and the liquid in the stomach, while having no resemblance to the ordinary table-drinks, was like the water in the ditch. In the expert's opinion, this water was swallowed during an attempt to drown the deceased; in support of this belief, Dr. Duriau cites "the well-established fact" that animals when held under water swallow considerable quantities of the fluid when the passage to the stomach is clear.

The theory thus formulated by the medical inspector was fully confirmed by the confession of the two culprits at their trial. They said that they first struck the deceased on the head and partially stunned him. They then threw him into the ditch and tried to hold him there; but he recovered sufficiently to resist their efforts and to escape from them temporarily. They seized him a second time, threw him down and strangled him with their hands; they then threw his dead body into the ditch.

Professor Brouardel, commenting on this case, when it was reported at a meeting of the Medico-Legal Society of France, said that, notwithstanding assertions to the contrary by many authors, it had been demonstrated experimentally that the fluid in which dead bodies are immersed does not penetrate, by gravitation, to the stomach.

(To be continued.)

### Therapeutical Memorandum.

#### CARLSBAD WATERS IN THE TREATMENT OF GOUT AND BILIOUSNESS.

BY J. B. FOTSDAMER, M.D., PHILADELPHIA.

Mr. J. B., aged sixty-nine, weight one hundred and ninety pounds, height five feet seven and one-half inches, had an attack of renal colic about twenty-two years ago. Oxalate crystals appeared in the urine. For a time his life was despaired of. Fifteen years ago he began to grow stouter, and had periods of depression. He consulted a physician at that time, who advised horseback exercise, otherwise serious results might follow. This instruction was not carried out. Eleven years ago, while being treated for a colles fracture, left, he had an attack of inflammatory rheumatism, confined to the right shoulder joint. Shortly after this he had another attack of renal colic,

<sup>2</sup> *Annales d'Hygiène Publique et de Médecine Légale*, January, 1896, page 83.

not as severe as the first one. Since 1860 he has had occasional attacks of muscular rheumatism, at times quite severe. In the early part of last year he began to complain of pain in the thumbs, which were swollen. He had pain in toes, but not so marked. The pain in the thumbs kept him awake at night. He takes very little exercise. Diagnosis: gout. He was put on a course of iodide of potassium, and the wine of colchicum seed, without beneficial results, although pursued for a long time. The salicylates were then tried, with the same result. Both the above methods were pursued in conjunction with a regulated diet. He was then placed on Carlsbad waters, the Sprudel being used. He drank three or four wineglassfuls a day, the water always being heated first. Beneficial results were noticed before beginning on the second bottle, as the patient was able to sleep at night. Improvement continued, and after six bottles had been used the pain was gone, and the swelling disappeared. At the present writing, six weeks after this treatment was begun, the patient is perfectly well, having used but ten bottles of the water. The only restriction placed upon Mr. B. J., while drinking the Carlsbad waters, was that he was not to drink any malt, and very little of spirituous liquors. This he did not carry out, as he drank about a glass of beer a day.

Mrs. S. B., aged forty-five, of full habit. Has had frequent attacks of biliousness. Was called in to attend her early last fall. Symptoms as follows: Complexion muddy; tongue coated with yellowish fur; bitter taste in the mouth; appetite poor; bowels constipated; some dizziness. Her feet are somewhat swollen. She was given small doses of calomel, followed by a saline purge. Bitter tonics were then administered. Jalap, fifteen grains, and cream of tartar, an ounce, were given about every four days, to keep the bowels open and to diminish the swelling of the feet. The patient improved, and I discontinued my visits. About six weeks later I was sent for, when I found a recurrence of the above symptoms. The patient is very stout. On physical examination I found the liver considerably enlarged. Carlsbad Sprudel water was ordered, in wineglassful doses four times a day, to be taken cold. The patient soon began to improve. After taking five bottles, is well. The swelling of the feet has disappeared, the bowels are regular.

Mr. S. H., aged forty; rather plethoric; exhibited symptoms similar to Mrs. B. Feet were not swollen, liver not enlarged. The same treatment was pursued, with a regulated diet; was well after taking three bottles.

### Reports of Societies.

#### MASSACHUSETTS MEDICAL SOCIETY. SUFFOLK DISTRICT. SECTION FOR CLINICAL MEDICINE, PATHOL- OGY AND HYGIENE.

ALBERT N. BLODGETT, M.D., SECRETARY.

DECEMBER 8th, 1886. Meeting opened at 8.00 P.M., DR. F. I. KNIGHT, in the chair. The reading of the records of the last meeting was omitted. The Chairman announced that Dr. W. N. Bullard would show a case of great interest before the commencement of the regular programme as announced on the cards of invitation. Dr. Bullard presented the patient and described the condition as that of

#### SYMMETRICAL ATROPHY OF THE LOWER EXTREMITY WITH BACKWARD DISLOCATION OF THE TIBIA.

A full report of the case will be published later.

The paper of the evening was by DR. MORTON PRINCE, and was entitled

#### THOUGHT-TRANSFERENCE AND SO-CALLED MIND- READING.<sup>1</sup>

PROF. JOSIAH ROYCE was invited by the Chairman to open the discussion, and began his response by citing a suggestion recently made to him by a friend (Mr. Barrett Wendell of Cambridge), to the effect that thought-transference, so far from being in any way a supernatural gift, or an extraordinary acquirement in addition to those attained by the average of persons, may be a persisting trait of a former less cultivated condition of the human race, and may therefore be a rudimentary characteristic, and an indication of retrograde nature, rather than a sign of advance. The nature of the phenomena reminds one in fact of those traits of the lower animals which are often grouped under the common name of "instinct," and which are seen to a marked extent in birds, as well as in many families of the lower beings. In man, this may have long been an obsolete condition, having been replaced by the higher attributes of human acquirement, particularly by speech, which has thus supplanted the ruder and more imperfect modes of communication formerly carried on by other and less comprehensive methods of conveyance of ideas. This suggestion of Mr. Wendell's is seen to be faintly indicated in the researches of the English observers, and the challenge has gone forth, and must be met. We find ourselves in the presence of unknown phenomena, which demand scientific investigation at our hands. The labors of so many intelligent and conscientious investigators must produce some result, and it is more than likely that the subject will be brought nearer to a logical and reasonable explanation than is at present the case. If in a certain period of time, perhaps twenty or thirty years, no advance has been made, it may then be said that the attempt of science to unravel the mystery at present surrounding this subject, has been a failure. Among the recent additions to our means of forming a judgment, may be mentioned the book just published by Messrs. Myers and Gurney, called "The Phantasms of the Living," an elaborate effort to collect and criticise the evidence for the supposed apparitions of living persons in places remote from those where they are actually present. Phenomena of this sort, if they were to be established, would be apt to suggest some sort of thought-transference as their true explanation. The narratives in which such events were described, seemed until recently to be mere folk-lore, yet the candid investigator must admit that at the present moment there is at least a chance of finding something more than folk-lore in such accounts. The challenge has here also been fairly made. Either these stories must upon examination turn out to be demonstrably worthless, or else some such phenomenon as thought-transference must be admitted as a fact. In any case, in the interests of the fair and free study of nature, we ought to consider such matters further. If the truth were known, it would surely prove to be not marvelous in the popular sense, not romantic, not of a sort to encourage superstition (for the truth of nature, once

<sup>1</sup> See page 108 of the Journal.

found, is always free from these faults); but it would doubtless prove to be important, for the truth of nature is always important. The speaker recommended the American Society for Psychical Research to the sympathy and to the scientific interest of those present. This body, he said, has undertaken to work in an independent and critical way in the field of these significant inquiries.

MR. T. W. HIGGINSON said that some light was thrown upon Prof. Royce's theory of the lower action of the mind in thought-reading by the fact that it so often seemed to involve a lower range of moral activity as well. He had given some investigation, many years ago, to the phenomena of mediumship and had practically abandoned the inquiry in consequence of the absolute impossibility of finding any firm foothold among the phenomena. The possession of abnormal powers was apt to be combined with a mental or moral state which destroyed all inclination for a scientific or even a candid examination. While the inquirer was always assured that the performers courted such investigation, it always proved in practice that all tests must be within such narrow limits as to be valueless. Thus, the Davenport brothers were tied with knots in their dark cabinet, but the knots must be at just such points and tied in just such a manner as the performers required. The only way to detect their deceit was, by apparent clumsiness, to spill some flour on the tied hand and then to exhibit the same flour on the curtains which the "spirit-hands" had pushed aside, and this the speaker had accomplished.

But these were the cheapest and most easily detected frauds. The speaker was inclined, while investigating, to put some faith in the so-called medium-power and certainly had experiences which went far beyond the recent instances of thought-transference, even if these last were wholly genuine. He had not only had his mind read, but things known and forgotten brought back to memory in spite of him; yet the moment any serious test was attempted, either the mediums or their controlling power had become evasive or silent. Those mediums who could accomplish anything shrank from anything like scientific investigation; and those who would submit to scientific investigation yielded nothing of any value. Worst of all, there was a *luxury* and slipperiness of moral principle. The most remarkable medium whom the speaker ever saw, had admitted to him, in conversation, that mediums possessing the real power were often tempted to eke out their performances by a little deception, in order to produce conversion in unbelievers. When asked if he himself ever did this, he could only say that he was so nearly unconscious during his trances, or so highly-wrought, that he could not positively assert that he had never yielded to this temptation.

No person accustomed to such investigations could help seeing in the late experiments of Mr. Bishop the professional demeanor characteristic of mediums and of the Davenport brothers. Welcoming inquiry at the outset, he immediately began to evade or resent it when practically applied. He certainly did remarkable things, but these were constantly vitiated by the attempt to deceive the senses of his audience and make them appear more remarkable still. Proposing in his circular to have contact with his associates in the carriage experiment, through eighteen feet of wire rope, he asserted up to the end that if he touched them personally it was through inadvertence. Yet those who

walked by the side of the carriage testified that the hands of the associates were on his head for much the greater part of the time. Such tricks as these render investigation practically worthless, and show the performer to be upon a low moral plane.

The speaker said that he had joined the Society for Psychical Research from a feeling of duty; but without expecting any dazzling results. The chief result thus far was to show how much more prolific was England than America in ghost-stories. The speaker was on the committee on apparitions and haunted houses, of which Prof. Royce was chairman: they had sent out many circulars and obtained very little. Prof. Lowell had lately said of the old buildings in America that they rarely looked venerable, that time refused to console them. Perhaps they were not to be consoled even with a ghost. Nevertheless, the speaker felt a certain pride in the few thin pamphlets thus far issued by the American Society; he felt proud of the pages that were *not* there, as compared with the thick reports of the English Society, containing a great deal that was hardly worth printing. The American reports, so far as they went, were the work of men of trained scientific minds and were a positive addition to the literature of the subject. The whole matter was eminently worthy of the attention of physicians; even the delusions, if they were such, were phenomena of the human mind, and hence within the domain of that profession whose province included both mind and body.

DR. C. S. MINOT was invited to continue the discussion, and spoke as follows: It has been my good fortune to be connected with the Society for Psychical Research, and to therefore know what is being done in the way of investigating the subjects presented before it. I have been much interested in the paper of Dr. Prince, and in the remarks of those who have preceded me. I have no criticism to make, and I think the subject has been very fairly presented before the meeting. All I can do, therefore, is to tell what the Society is doing, and the results which have been accomplished through its efforts. The English Society has made a large number of experiments in the attempt to discover the source of the phenomena associated with so-called mind-reading. Here in America we have made some thirty thousand such experiments, but thus far have attained no noteworthy results. The efforts of our Society in the direction of thought-transference have not been crowned by any conclusions of value. The theory which was followed was that, if such a thing as thought-transference occurs at all in any person, it must occur to a certain extent in all persons, or in, at least, a great many persons. The observations were distributed by the mathematical calculations of the chances in such cases. The cases were all failures, with one single exception. It has been discovered that the thoughts of all persons follow a definite system in relation to the digits, so that in an experiment consisting of the determination of numbers, it is possible to know the probable system which will unconsciously be adopted by the person making the test, and thus an important aid is obtained to the correct solution of the problem. The tests of so-called investigators have often been rendered quite unreliable by the fact that they were themselves the dupes of their own ideas. The English Society is in that condition. They ask of us a tremendous act of faith, as the foundation of all further action. Nothing so stu-

pendous has ever been known in any scientific investigation which has ever been attempted. We cannot accept the conditions thus imposed upon us, which would operate to restrict both the means and the methods of investigation. We, as good men, may accept the *best* we have, believing that nothing is impossible simply because it has not yet been accomplished, and accepting nothing as positive which has not yet been proved.

The human mind is capable of but limited power of attention, and it is often quite oblivious to phenomena which take place within the perception of the senses, when the attention is powerfully diverted and held by some strong impression. Thus Coleman Sellers requested Professor Leidy to clasp his hands tightly, and to maintain them in this position. The curtain was drawn for a short time, and though Professor Leidy stoutly maintained that he had not moved his hands, yet it was found that his coat had been removed without his knowledge. The explanation of this occurrence is that the attention of the subject has been diverted from what he was endeavoring to accomplish, and the coat had been removed while his attention was held in another direction. The power of attention is a defective power, which the conjurer knows how to control, and he finds his skill in the ability to abstract the attention of the subject. We are very imperfectly acquainted with the power of the senses, which is something truly prodigious. Every one has heard of the hypnotized boy in Paris. This youth, when in the condition of hypnotism, read a page of printed matter from the reflection of the page from the cornea of a person who was looking at the page, the boy being placed in front of the reader, with the back of the book toward him. The picture made upon the surface of the cornea of the reader occupied an area of but one-tenth of a millimeter, yet the sense of sight in the youth was so acute under the condition of hypnotism, that his eye was able to discern the printed matter upon the reflected picture of the page, even under the trying conditions mentioned above.

To further test the power of the senses, a piece of wood was given to the youth, and he was directed to make a drawing of it. The picture which he made was a correct representation of the appearances of the wood, but of microscopic detail. In fact, it was a picture of the microscopic structure of the wood. Such experiments as these were unknown to the English investigators, and their results must not be looked upon as conclusive. We should withhold our ultimate decision until we know much more than we know at present. The phantasms of which so much has been written and said of late, possess little in the way of diversity or novelty. The subjects all tell the same story, subject only to variation of time, and place and persons. The facts are always the same. The subject of folk-lore is another interesting theme of investigation. We have all heard of the witches of olden times. They came here in great numbers, and wrought great mischief among the people. Good people saw them, recognized them, suffered from them, and feared them. The witches all followed a certain programme, and it was always known what they might be expected to do. The present condition of things is that of the survival of small remnants of folk-lore in our time, which are the subject of mystery and fraud.

Brain-waves are hardly capable of explaining the tricks often referred to this source. The brain has

no means of receiving impressions other than by the aid of some one or more of the senses. We know of no other method of communicating impressions to another individual than by means of the recognized channels of sense-perception. If other modes of perception exist, they have not been discovered.

The following letter was read by the Secretary:

HARVARD COLLEGE OBSERVATORY,  
CAMBRIDGE, December 5th.

DR. ALBERT N. BLODGETT, 138 Boylston St.

My Dear Sir: I much regret that other engagements will deprive me of the pleasure of accepting your invitation to attend the next meeting of the Section for Clinical Medicine. I have only one suggestion to make regarding the phenomena of muscle-reading. The case is greatly simplified when the transmission takes place through a wire connecting the agent and percipient. In this case it is not probable that any action takes place, except a variation in the tension. Such a variation ought to be capable of detection by mechanical means, of which the simplest would be a spring-balance. For the rare sensitiveness of a professional mind-reader, a substitute could thus be provided which could be used by any experimenter. Since muscle-reading is a purely mechanical phenomenon, it seems to me that its existence ought to be established by mechanical means. I hope that Dr. Prince's paper may get into print, for the benefit of those who, like myself, will be unable to hear it read.

Very truly yours,

EDWARD C. PICKERING.

DR. P. C. KNAPP said that he had listened to the remarks of Dr. Minot, and found in them the explanation of ideas which, in a vague way, had been floating in his own mind. The suggestion made by Professor Royce, that the phenomena observed in the so-called mind-reading may be a rudimentary condition, or a return toward a primitive state of mental development, seemed to Dr. Knapp to be a valuable one. The condition in which the phenomena are observed may be similar to that of hypnotism, and to certain other allied conditions sometimes observed as pathological states of the mind. In England, only a few people are capable of thought-transference, and are often the subjects of morbid mental or moral conditions.

The subjects of hypnotism are classed by psychologists as "*degeneré*." From a purely medical standpoint, there is much interest in the community in this subject. It has long been a source of curiosity to the public. The investigations which have been made show that those persons who possess the power to carry out the features of mind-reading are, without exception, such as would be classed as weak-minded. They thus fall into a similar category to that of the subjects of hypnotism.

DR. PRINCE, in closing the discussion, alluded to the contrary results obtained by English and by American observers, as tending to show that either the English people were more susceptible to the condition, or that the observers were misled. There is a limited susceptibility to morbid states. Thus only one person in twenty can be mesmerized; but in our experiments we have made thirty thousand experiments, with notably few results. The Creery children, who possessed the most remarkable powers while young, lost their power as they approached maturity. Their power was, therefore, either a rudimentary mental condition, or it was deception.

Adjourned at 10.15 o'clock.

— The most effective, as well as most convenient cure for warts is said to be fifteen grains of corrosive sublimate dissolved in an ounce of collodion, the warts to be brushed carefully with the mixture once daily.

THE BOSTON  
**Medical and Surgical Journal.**

THURSDAY, FEBRUARY 3, 1887.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 283 Washington Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES, UPHAM & COMPANY,  
 283 WASHINGTON STREET, BOSTON, MASS.

NERVE-STRETCHING.

A WORK has recently appeared<sup>1</sup> on the important practical subject of nerve-stretching which we can commend to our readers as a model of conscientious criticism. The writer has collected, with the aid of the *Index Medicus* and other books of reference, all the cases on which he could lay his hands, deliberately omitting, however, those which were not given in sufficient detail to justify a fairly accurate opinion. The whole number of cases summarized is four hundred and fifteen, and a digest of each one is given in the appendix. We will first give an outline of the writer's conclusions, and will then indicate briefly the grounds on which his opinion as to the different points is based.

1. The action of nerve-stretching as a therapeutic measure differs in kind from that of other operations on nerves (neurotomy, neurectomy and compression). Its influence makes itself felt even in the nervous centres, especially the spinal cord, and it is to this that it owes its power of modifying the sensory functions of the nerves, without materially affecting their motor functions.

2. This action of nerve-stretching on the nervous centres may give rise to hemorrhages and inflammatory changes, both acute and chronic, and often very severe.

3. The operation is therefore to be regarded as an agent of greater therapeutic power than the other operations on the nerves, and also as much more dangerous, and it should not therefore be lightly resorted to.

4. In general terms, it is only suitable for mixed nerves, section or resection being preferable for sensitive nerves. This statement is, however, in need of certain qualifications.

5. Thus, in the treatment of neuralgias of the ophthalmic division of the trigeminal nerve the results of

<sup>1</sup> *Valeur Thérapeutique de L'Elongation des Nerfs* par Le Dr. Félix Lagrange, Professeur Agrégé à La Faculté de Médecine de Bordeaux. For a reference to earlier observations on this subject, see also this Journal for January 16th, 1884.

resection and stretching are about equal, so far as the frontal and nasal branches are concerned. In case of the nasal, in fact, the operation of stretching, or, better, of complete evulsion, is to be preferred, as being relatively harmless, easy of performance, and in some respects more effective. This measure has proved of some benefit in chronic glaucoma, and of still more benefit in acute glaucoma. It is also of great value in the treatment of acute or chronic ciliary neuralgia.

6. The operation of resection is preferable for the infra-orbital neuralgias and may in case of need be extended so far as to take in Meckel's ganglion. Resection is also the best operation for the dental nerves.

7. The stretching of mixed nerves is justifiable in obstinate cases of neuralgia but the less dangerous method (applicable only to the sciatic), is that in which the stretching is accomplished by forced positions of the limb. As a means of treatment of locomotor ataxia and the different diseases of the spinal cord, nerve-stretching is of so little value as to be unjustifiable.

8. Tetanus can be treated with equal success and more safety by neurotomy, or compression of the nerves than by stretching; and (9) the same is true of torticollis.

10. Stretching is of some value in contractures and spasms of traumatic origin, and in reflex epilepsy.

11. Lepro-anaesthetica is not benefited by nerve-stretching except as regards the pain, and even this effect is not to be counted on; neither can atrophy of the optic nerve be helped in this way.

The first two of these propositions are supported partly by physiological, and partly by clinical arguments. With the former, we will not undertake to deal, except so far as to say that in experiments upon animals in the laboratory, lesions have been found in the spinal cord similar to those observed in men, besides interstitial neuritis of the nerves operated on. We cannot wholly agree with the writer in regarding it as proved that an action on the nervous-centres is the peculiar and essential feature of nerve-stretching, but whether the therapeutic effect of nerve-stretching implies this action or not, the list of cases in which such an action has been produced, to the patient's evident injury, is enough to inspire serious thoughts of caution; and the more so that this list is probably very incomplete, partly because disastrous results are often left unrecorded, and partly because those which only show themselves after the lapse of some time are often unrecognized.

Fourteen cases of serious results are reported, many of them ending in death. Briefly stated, these observations are as follows:

1. Case reported by Hirschfelder; locomotor ataxia; stretching of both sciatics; epileptiform attacks immediately after the operation; two days later somnolence and coma; death on the fourth day. 2. Reported by Cavalry; locomotor ataxia; stretching of the left sciatic; relief from pain for one month; recurrence of pain; two months later acute myelitis; epilepti-

form convulsions; coma and death. 3. Reported by Gussenbauer; death after the end of six weeks; with the symptoms of pyelo-nephritis. 4. Reported by Westphal; stretching of the sciatic nerve; diffused softening of the spinal cord in scattered spots. 5. Same; stretching of the crural nerve on one side; paralysis of both sides including the sphincter; improvement; transverse myelitis; death. 6. Reported by Rumpf; locomotor ataxia; stretching of both sciatics; death on the ninth day and hemorrhage into the cord. 7. Reported by Weltrubsky; locomotor ataxia with cystitis; nerve-stretching; increase of the disorders of motion and sensation; death on the thirty-eighth day from purulent nephritis; hemorrhage beneath the membranes of the cord and signs of inflammatory process. 8. Reported by Kulenkampf; locomotor ataxia; stretching of both sciatics with thorough antiseptic precautions; paralysis of the vesical sphincter immediately after the operation; phlegmonous inflammation of the right side; death. Extensive suppuration was found along the sciatic nerve, but no recent lesion of the cord which seemed capable of explaining the paralysis of the sphincters. This result has, however, been several times reported, as for example in a case (10) by Obalinski; locomotor ataxia; stretching of the crural nerves; paralysis of both sphincters; death in two weeks. 11. Reported by Podrez; locomotor ataxia; stretching of both sciatics; ten days later severe trophic disorders; gangrenous eschar; death in six weeks. 12. Reported by Fenger; locomotor ataxia; stretching of both sciatics and both crurals; relief from pain, followed by eschar of the sacrum, pyemia and death. 13. Reported by Mickulitz; multiple sclerosis of the spinal cord; nerve-stretching; death very shortly afterwards. It is not only where large nerve-trunks are stretched that such results are seen. 14. Oberlinski has reported a case where the patient died rapidly in coma two days after the stretching of the intercostal nerves.

Among lesser accidents may be mentioned neuritis of the nerve stretched. Ulcerative keratitis followed stretching of the inter-orbital nerve in one case, an accident which has never been reported, to say the least, as the result of a resection of this nerve. Six cases are described of permanent paralysis due apparently to injury of the nerve itself; Gillette reports a case of nerve-stretching for sciatica followed by the disappearance of the specific pains, but shortly after, by the onset of neuralgia elsewhere which had previously not been present; and the same author gives us a second case of similar history.

Not even yet is the catalogue of possible mischances complete. Several cases have been reported where the nerve has unexpectedly ruptured, probably because it had become weakened by morbid changes, the extent of which had not been appreciated. Once death occurred from the entrance of air into the veins, and once from pulmonary embolism, resulting from thrombosis of the right femoral vein. Professor Verneuil had one death from rapid phlegmonous erysipelas.

Berger reports a similar result, although the operation had been conducted with full antiseptic precautions, and it is a fair question whether this was not due to an impairment of the vitality of the tissues, caused by injury of the nerve or nerve-centres, since similar accidents (deep suppuration) have been reported also by others.

It is noticeable that in almost all the most serious cases the spinal cord had been previously diseased, and it may be that but for this the nerve-stretching would not have produced disastrous results. It must, however, be borne in mind that we can rarely be sure that we are dealing with a perfectly healthy case, nor can we accurately gauge the degree of irritation that we set up. In the case of the sciatic nerve, the method of stretching by a forced position of the limb ("bloodless-stretching") is considered less dangerous than the operation which was done in the cases above cited; and the writer says that, in fact, this has not been reported as having been followed by any serious lesions of the nervous centres. It has, however, been demonstrated that the traction produced in this way actually displaces the spinal cord, and it is not, therefore, to be looked upon as an operation to be resorted to without hesitation. Furthermore, we have ourselves seen a severe neuritis lighted up in this way in a case of sciatica of several months' standing, and no longer presenting acute symptoms.

The writer next studies the therapeutic value of the operation for the different nerves of the body, with the results stated in the propositions 5, 6, 7, and 10, given above.

Without attempting to follow him at length through the remainder of his argument, we will call attention to one or two points. It is often advised that when the different branches of the fifth pair are operated upon, even if resection is the final intention, stretching should first be employed as an additional precaution. The analysis made by Lagrange renders it probable that we do not in this way materially improve the chances of success, while at the same time we do introduce a new element of danger. It must be, in fairness, acknowledged, however, that, inferences and theoretical considerations apart, the cases actually reported do not show this danger to be great, since out of forty-nine cases of stretching of the different nerves of the face, no more serious accident than suppuration, which was eventually recovered from, is reported, and this only three times, except the single case of ulceration of the cornea mentioned in the text. We have not had the opportunity of referring to the details of a communication to which the writer refers, made by Nicaise to the Société de Chirurgie, in which traction on the cranial nerves is spoken of as especially dangerous, on account of their nearness to important central organs.

The actual showing of the cases of stretching of the superficial mixed nerves, not attended by disease of the spinal cord (see above), is also rather favorable to the operation. Ninety-eight such cases are recorded, of

which sixty-eight were operations on the sciatic. There was only one death (stretching of the intercostal, see above), and a few cases of deep suppuration and temporary paralysis of the sphincters.

The successful results, so far as the cases were followed, were in the great majority; but, unfortunately, few of the patients were under observation long enough to test the question of the recurrences of the pain, and the appearance of secondary disorders of the spinal cord.

In view of the serious results in such a large proportion of the cases of locomotor ataxia, it is urgently desirable that surgeons should furnish us with the means of judging about the final outcome of the operations for neuralgia also. The former cases, it must be remembered, were so much before the public eye, that the results in them were sure to be made known.

For one set of cases, it seems to us that Lagrange distinctly overrates the value of nerve-stretching, and that is the cases of facial spasm. An unprejudiced examination of the final reports, as given by Bernhardt, Keen, and others, makes it plain that stretching of the facial nerve is practically valueless as a means of permanent cure.

It is well known that the attempt has frequently been made, with occasional benefit, to treat clonic torticollis by stretching the external branch of the spinal accessory, and the writer does not bring forward absolute demonstration of his belief that this operation is a dangerous one from its action on the nervous centres. All that we know, however, of the clinical history of these local clonic spasms points to the conclusion that whatever benefit is gained in them by operations upon nerves is due mainly, if not wholly, to an interruption of conduction through the nerve-trunks. The muscles supplied by the external branch of the spinal accessory, fortunately, receive also filaments from other sources, and, therefore, resection of the spinal accessory is not followed by complete paralysis, and is not likely to prove more permanently useful than the stretching, while it also is without the danger which theoretically attends the latter operation.

#### MEDICAL EXPERT TESTIMONY.

In a recent editorial (January 20th, 1887,) we made reference to the hardships to which the members of the medical profession were liable to be subjected in suits for malpractice. One of the methods of action proposed as tending towards the alleviation of the unjust position in which medical men find themselves, when defendants in such suits, is the regulation of medical expert testimony. Every medical man who has been obliged to act as an expert in any case in the courts, and how few there are who have not at one time or another been called upon to do so, knows from personal experience in what a false and unfair position the expert is placed. However scrupulously honorable, however desirous of justice and fair play

he may be, and we believe that a very large percentage of all our experts are of this character, the medical expert is, by the very conditions under which he is placed often forced into the position of an ex-parte witness, only differing from the ordinary witness in the nature of the evidence which he is expected to give and in the size of his fee. Called by one party to the suit, consulting more or less frequently with those interested in one side of the case, the expert himself is liable after a time to become unconsciously imbued with their views and his opinions are apt to be involuntarily modified by the surrounding influences; and this is of importance since the subject of his testimony is opinions rather than facts.

Yet this is but a small factor in the injustice of the position. As at present regarded the medical expert is rather expected to make an ex-parte statement. Not long ago at a dinner given in honor of one of the most able and distinguished physicians we know, the following anecdote was related: Two gentlemen were walking down the street in earnest conversation in regard to a suit in which medical expert testimony was required. One of them asked the other, "Shall you summon Dr. — as expert on this suit?" "Oh no," was the reply, "certainly not, you never can tell which way his testimony will go." So long as in the public opinion it is considered just and right to know in which way the expert testimony will go, so long will it be very difficult for medical experts to give their opinions without at least unconscious prejudice.

Again, if experts were permitted in all cases to make a full statement of their views and opinions in regard to the subjects on which they were consulted, the evil of the present system would be much lessened. But this is not so. They are called upon simply to answer carefully-framed questions and skillfully-built hypotheses, and the jury in many cases is in no position to appreciate the force of the answers, while the physician has constantly to be on his guard lest by some remark, but partially understood by the jury, he may convey the opposite impression from that intended.

Medical expert testimony in most of our States has now, in consequence of these things, reached a low level in the public estimation as well as in legal circles. This may be due in a small part to the fault of the profession itself, but the principal cause is the unfortunate, the unfair, and we might almost say, the dishonest position in which the expert is placed by our present system of trial.

To remedy this, various measures have been suggested. The excellent pamphlet of Mr. Clement Herschel, "On the best manner of making use of the services of experts in the conduct of judicial inquiries," has been printed by the direction of the Bar Association of the City of Boston. It is a powerful argument in favor of a change in the system of summoning experts, and it gives a *résumé* of the practice in England and Germany. As a result of their consideration of this subject, the Committee of the Bar Association on

the amendment of the law has already voted to recommend to the Council that action be taken favoring the passage by the Legislature "during the coming session" of the following bill in relation to medical expert testimony :

**SECTION 1.** In any action, suit or proceeding, civil or criminal, in which the testimony of a medical expert witness is desired by either of the parties, the court or any judge thereof in chambers, or in vacation, in any county may designate one or more proper persons learned in the science of medicine, to be summoned as such expert witness: and the clerk shall thereupon issue a subpoena.

**SECT. 2.** Such witness shall be paid for his attendance, travel and services, including services in preparation, a reasonable compensation to be allowed by the court and paid out of the treasury of the county.

**SECT. 3.** In any criminal proceedings the defendant may call and examine other expert witnesses in addition to those hereinbefore provided for, but at his own cost, and in such cases other medical expert witnesses may be called and examined by the Commonwealth.<sup>1</sup>

**SECT. 4.** No medical expert witness shall be admitted to testify before any court or magistrate, except as hereinbefore provided.

We hope that some movement in this direction may prove successful. It should be distinctly understood that the bill above quoted has thus far only been recommended by the Committee to the Council of the Bar Association and has not yet been approved by the Council. We understand, however, that a bill of similar character is now before the Judiciary Committee of the Legislature.

#### REPORT OF THE SURGEON-GENERAL OF THE ARMY.

THE report of the Surgeon-General of the Army for the fiscal year ending June 30, 1886, has just been issued, and contains the usual amount of statistical information and other matters of interest. The recommendation that Congress grant authority, in the purchase of medical and hospital supplies which cost less than \$500, that such purchases be made after due advertisement for bids, without entering into a formal written contract, is a movement in favor of greater simplicity and directness. In many instances a strict compliance with the letter of the law and existing regulations, in preparing the formal executory contracts, *five copies of which are required*, entails an expense to the Government in clerical time and labor fully equal to the cost of the article for which the contract is made. It is not believed that such was the intention of the framers of the laws relating to purchases of Government supplies.

It is proposed to add to the literary work which the medical department of the army has already accomplished, or, at least, it is considered very desirable to do so by the publication of a catalogue of the museum. Such a catalogue, with proper illustrations, will make three large volumes, and will be of great benefit to the medical profession as well as to the museum itself, and it is respectfully recommended that

authority be granted by Congress for printing this work. The preparation of the manuscript of Volume VIII of the Index Catalogue is well advanced, and the first part of it is now going to press.

The publication of the third medical volume, the last of the series composing the Medical and Surgical History of the War, has been delayed by the pressure of current work at the Government Printing-office. The manuscript was ready for the press in February last, but little progress was made in printing during the continuance of the session of Congress. All the plates, diagrams, and other materials for the illustration of the volume are on hand, and page-proofs of the first hundred pages of the work have been filed in the Surgeon-General's office.

The acting Surgeon-General reiterates the necessity for the organization of a hospital corps, by the enlistment of able-bodied and intelligent men, who shall be thoroughly trained and instructed as cooks, nurses, attendants, and litter and stretcher bearers, thus preparing the Medical Department for any emergency of peace, war, or epidemic.

The report is signed by J. H. Baxter, as acting Surgeon-General, U. S. Army.

#### ANNUAL REPORTS OF THE PRESIDENT AND TREASURER OF HARVARD COLLEGE, 1885-86.

THE portion of this report relating to the Medical School is that which especially concerns us and our readers, and we accordingly turn to it immediately. On the principle of "blessed that country whose annals are few" the Medical School of Harvard University must be regarded as very prosperous. Out of twenty-four pages of the President's report the Medical School gets less than one; a more distinguished treatment, it is true, than that allotted to the Divinity School, but less so than the Law School receives. Moreover, the impression of a sleek prosperity, derived from the meagre annals, is increased, when we learn elsewhere in the President's report that both the Dental School and the Veterinary Department are really dependent upon the gratuitous assistance which they receive from the Medical School for their existence. As for the Medical School itself, apparently all it now needs is "income enough to enable it to make full use of the facilities which its excellent building affords for laboratory investigations connected with medicine." The Law School, on the other hand, though acknowledged to be in a position of great strength, the proof of which is given in detail, it is announced: "needs more teaching and more scholarships. A professional school of high grade ought not to depend on tuition-fees for nearly two-thirds of its annual expenses."

And yet the Law School with an attendance of one hundred and fifty-eight students during the year, and not requiring laboratories, has invested funds amounting to \$176,898, yielding with one-quarter of the Bussey trust an annual income of \$12,851; whilst the

<sup>1</sup> Section 3 is inserted only to meet the possible objection of the unconstitutionality of the bill in its application to criminal cases.

Medical School, with an attendance of two hundred and seventy-two students and the much more expensive machinery required for their education (to say nothing of the aid extended to the Dental and Veterinary Schools), has an invested fund of only \$181,000, yielding an annual income of \$10,333.

To say the truth, whatever the needs of other departments or other schools of the University, we believe there are none which require endowments more seriously than the Medical School, and there are none from which there would revert to the public so immediate and so handsome a return upon its gifts. Moreover, it is in the departments for clinical instruction that such funds are most needed. The branches dependent upon laboratory work and instruction were those most benefitted by the erection of the new and admirable building for the School. We believe the University has no more devoted or self-sacrificing teachers in its whole corps than those connected with the clinical branches of the Medical School. Were it not for this devotion on the part of a large number of men occupying hospital and dispensary positions, some of whom are in no official relation to the School and receive no mention in the reports, the clinical instruction of the School would come practically to a standstill. At the present time the two very important Professorships of Clinical Medicine and Therapeutics are vacant, and during the year 1884-85 one professor filled the two chairs. We do not undervalue the necessity of laboratory training in making good physicians or of laboratory work in advancing the science of medicine, but after all said and done the patient remains as a very large part of the equation to be solved, and he must still be studied, sometimes as a type, but much more often as an individual by and for himself.

Of the whole number of students in attendance during the year (272) 148 had literary or scientific degrees, a very encouraging proportion. There were 70 applicants for the degree of doctor of medicine in the three years' course, of whom 11 were rejected; there were nine applicants for the degree in the four years' course, of whom two were rejected. There were 18 students in the fourth class, only one half, therefore, came up for a degree.

The Medical Faculty have laid before the Academic Council a plan for the abridgement of the college course by those students who go from college directly into one of the professional schools of the University, with a view to avoiding the too advanced age at which graduates of colleges or scientific schools begin the study of medicine, and the consequent unreasonable postponement of entrance into practice, especially if a thorough course of professional study is pursued. We shall revert to this very vital issue at some future time.

— If Queen Victoria does not celebrate her jubilee by a liberal assistance to the London hospitals, it will not be for lack of sufficient reminders from the medical press of England.

#### COCAINE IN THE INCOERCIBLE VOMITINGS OF PREGNANCY.

COCAINE has lately come into use for the incoercible vomitings of pregnancy, and in several cases reported by Weiss, Engelmann, Holtz and Bois, it seems to have given good results. Weiss prescribes a teaspoonful every half hour of a solution containing fifteen centigrammes of hydrochlorate of cocaine in one hundred and fifty grammes of water. Engelmann and Holtz use a three per cent. solution in ten to thirty drop doses, while Bois applies to the neck of the uterus, night and morning, a pomatum in which one centigramme of cocaine is incorporated with fifty grammes of vaseline. Fraipont prefers the hypodermic method, injecting under the skin a Pravaz syringe full of a four per cent. solution, and claims signal success in other forms of obstinate vomiting, as well as in the vomitings of pregnancy.

#### MEDICAL NOTES.

##### NEW YORK.

— Mrs. Cornelius Du Bois has recently started a fund for sending out trained nurses from the school in E. 36th St., to care for the poor in their homes, and Mrs. Cornelius Vanderbilt has contributed \$1,000 towards it.

— The Alumni Association of the Medical Department of the University of the City of New York held its sixteenth annual dinner at Delmonico's on the evening of January 27th, when Dr. F. R. S. Drake presided, and the annual toasts were responded to.

— Small-pox has become increasingly prevalent of late, and, in consequence, six extra sanitary inspectors have been appointed to assist the present force of the Board of Health in arresting its progress. The disease has been rare in New York since 1882, when 708 cases, with 259 deaths, were reported from it. In 1883 there were but 26 cases reported, with 12 deaths, and in 1882 there were but 5 cases, and not a single death. In 1885 there were reported 105 cases, with 26 deaths, and in 1886, 109 cases, with 31 deaths.

— At the last meeting of the Medical Society of the County of New York, a paper on the "Relations of the Board of Health to the Medical Profession in the City of New York," by Dr. John C. Peters, was read by the Secretary. Dr. Peters claimed that the relations between physicians and the Board of Health were always disagreeable from the fact that at the head of the Board, as required by law, was a layman, and not a medical man. He urged that a bill be drawn up making it essential that the head of this department should be a regularly qualified physician. Dr. Peters asserted that the Board persistently refused to inform, as it is required by law to do, the Board of Education of the prevalence in any locality of contagious disease. As to its examination of the nuisances of the Croton River and its tributaries, he said that amounted to nothing, because the State Board of Health was not communicated with, and was consequently powerless to remove the sources of impurities.

### Miscellany.

#### THE OUTBREAK OF CHOLERA IN BUENOS AYRES.

The weekly abstract of sanitary reports issued by the Marine Hospital Service, and dated January 27th, contains an interesting extract from the dispatches of the United States Minister at Buenos Ayres concerning the outbreak of cholera in that country. It seems that cholera made its first appearance about November 1st, and was imported by the Italian ship "Persico," plying between Genoa and Buenos Ayres. The ambassador of the Argentine Government in Italy was a passenger on the ship, "and the anxiety to secure him an immediate landing, on the part of the ship's commander, seems to have so far overcome his sense of duty that, by concealed or garbled reports, he managed to turn loose, on Argentine soil, first here, then at Rosario, a great many persons from an infected ship. The testimony of passengers shows conclusively there was nearly a score of burials at sea of those who died of cholera on the voyage."

The disease was most fatal at Rosario, a city of commercial importance 200 miles from Buenos Ayres, where, out of a population of about 50,000, there were at one time from 35 to 50 deaths daily.

The United States Consul at Buenos Ayres, under date of December 10th, states that "while a few cases of cholera are still reported in each day's bulletin, the disease appears to have pretty much run its course at this port. On yesterday, up to ten o'clock, only one new case had occurred in the city proper, and two cases on board a steamer at Boca port. In the interior of the country, however, the disease has made its appearance, and in some places with a marked type. On the 4th instant, there were 13 deaths at Rosario, and 14 new cases, and at Cordoba 2 deaths and 5 new cases. The authorities feel assured that the prompt and rigid measures taken to stamp out the disease will prevent it from becoming epidemic. In all bills of health now issued by me I note the fact that cholera exists in this port, but apparently not in epidemic form."

#### TRANSMISSION OF HYDROPHOBIA BY THE INTENSIVE METHOD.

In connection with the charge of M. Peter, before the French Academy, that the death of the man Réveillac was very likely due to hydrophobia caused by Pasteur's "intensive inoculations," it is not amiss to quote some of the conclusions arrived at by Professor von Frich, of Vienna, as the result of laboratory experiments with the virus of rabies obtained from M. Pasteur for that purpose. Among other conclusions reached von Frich, states the following: (*Lancet, Vienna Correspondent.*)

1. Animals which have been subjected to hypodermic injections of a series of virus attenuated by desiccation become refractory to the stronger virus by the previous inoculations with the weaker virus if the stronger virus have not been used in too rapid succession. 2. Animals which have been inoculated hypodermically during ten days with virus of progressive virulence (medulla from ten days to one day) have not been refractory to infection with the fresh virus of street rabies, and have only exceptionally escaped after intra-cranial infection. 3. Rabbits and dogs

inoculated by trephining with the virus of street rabies of sixteen days' incubation have always succumbed, notwithstanding the preventive treatment already described. 4. M. Pasteur attributed to the method of slow vaccinations the unsatisfactory results obtained previously by M. von Frich, and recommended a more intensive mode of treatment. The experiments carried out conformably to M. Pasteur's instructions have given no more favorable result; all the animals died of rabies. 5. The experiments have demonstrated a most important fact—that is, that in the rapid process the weaker preservative medulla do not confer the same certainty of immunity from the effects of inoculation with the stronger medulla. Of a series of dogs and rabbits inoculated as a control-experiment to that described in the preceding paragraph, and in which the rapid process was carried out without previous infection, most of the animals died of rabies. 6. Most of the animals which were submitted to the preventive treatment after subcutaneous inoculation with street rabies, died of the disease even when the period of incubation was thirty-four days. These experiments show, says M. von Frich, that Pasteur's method of rendering animals refractory to rabies is not yet either sure or certain. There is not yet a sufficient scientific basis for the application in man of a preventive treatment after the bite of a rabid animal. It is, moreover, quite possible that the preventive treatment, at any rate the intensive method recently recommended by M. Pasteur, may itself transmit the disease.

#### OBITUARY.

##### SILAS EMLYN STONE, M.D.

The County of Norfolk loses a valuable citizen, and the medical profession of Massachusetts one of its most useful members, by the death of Dr. S. E. Stone, which occurred January 29, 1887, from uremia, at Walpole, Mass. He was a model of the well-educated country physician. His nicely-balanced mind, superior judgment and intelligence, strong sense of duty, — his self-respecting and calm, but always pleasant demeanor, and perfect equilibrium, — secured him high and appreciative estimation in a community which had known him from childhood, and among whom he had practised for a quarter of a century.

Dr. Stone was appointed assistant-surgeon of the Twenty-Third Massachusetts Regiment almost immediately after taking his medical degree. He nearly died of a fever contracted in the service, and came back to Walpole to be prostrated shortly afterward by a peri-nephritic abscess which again threatened to destroy his life. From this last-named casualty he never wholly recovered; but in the vacations, which his impaired health every now and then rendered necessary, he acquired much applicable knowledge of men and the thoughtful experience of an extensive and observing traveller which greatly added to his usefulness as a practitioner.

He was always alive to the interests of his native town. His admirable paper on "Charlton," a disease which repeatedly occurred in a hair-factory at Walpole, is well known to the profession. The firm and heroic stand which he took between the operatives and the factory owners at the time of a serious epidemic of that disease, — compelling the latter to thoroughly disinfect the raw material used, regardless of cost; a measure which put an end to the fatality attendant on handling certain kinds of hair, and prevented threatened riot and destruction, — is not so well known as if it had been the act of a less modest individual.

The removal by death of such a physician, in the prime of life, from his circuit of practice in a neighborhood so distinctly rural as that in which he lived, is a calamity to his medical neighbors and to his personal friends at a distance not less than to the locality itself. It is equally a misfortune to the public in general, which can ill afford the loss of professional men whose lives are worthy of the praise due to that of Dr. Stone.

##### WILLIAM THORNDIKE, M.D.

Dr. William Thorndike, formerly of Beverly, Mass., but for the past twenty-one years a resident of Milwaukee, Wis., died in the latter city on the 29th inst., of double pneumonia, aged fifty-one years, six months. He was the son of Albert Thorn-

dike, of Beverly, formerly president of the Eastern Railroad. In 1854 he was graduated from Harvard College and in 1857 from the Harvard Medical School. Dr. Thorndike began practice in his native town after service at Rainsford's Island and at the Massachusetts General Hospital. In 1862 he was commissioned as assistant surgeon in the Thirty-fourth Massachusetts Volunteers (Col. George D. Wells) and was soon made surgeon of the Thirty-ninth Massachusetts, serving in that capacity until the regiment was mustered out at the close of the war. He leaves three sons, the eldest of whom is pursuing the study of his father's profession.

## LUDWIG BANDL.

The death of Professor Ludwig Bandl, who was appointed last summer to succeed Breisky in the Chair of Obstetrics and Gynecology at Prague, took place early in December. He was perhaps mostly widely known to the profession in America in connection with his views regarding the uterine contraction-ring to which his name was given, and as to which, whether it reached the true internal os or not, a vigorous discussion has ever since been maintained. His writings upon the "Mechanism of Rupture of the Uterus," and upon the "Diseases of the

Tabes of the Ligaments of the Pelvic Peritoneum and the Pelvic Cellular Tissue, including Extrauterine Pregnancy," are well known to our readers. He had been *privat-docent* instructor in the Vienna Polytechnic, and Professor Extraordinary of Gynecology in the University of Vienna.

## Correspondence.

## TRANSLATION REQUESTED.

BOSTON, January 27, 1887.

MR. EDITOR:—The following message was left on my slate, showing the necessity of required Greek.

ο αναγκαιος εστι χρησθαι διδαξε λεγα

I have waited a long time to see if the writer would appear. He has not. I wonder how many of the JOURNAL readers can translate. Yours truly, B.

## REPORTED MORTALITY FOR THE WEEK ENDING JANUARY 22, 1887.

Massachusetts Towns . . . . .	—	—	—	—	—	—	—	—

Deaths reported 2,291: under five years of age 845; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas and fevers) 371; acute lung diseases 428; consumption 345; diphtheria and croup 165; measles 95; diarrheal diseases 24; typhoid fever 24; scarlet fever 22; whooping-cough 13; malarial fever 12; erysipelas seven; small-pox four; puerperal fever two. From typhoid fever, Philadelphia 11, New York four, Baltimore and Pittsburgh three each, Boston, New Orleans and Lawrence one each. From scarlet fever, New York 11, Philadelphia five, Brooklyn, and Pittsburgh two each, Baltimore and Lawrence one each. From whooping-cough, New York six, Baltimore two, Philadelphia, Brooklyn, Pittsburgh, Lawrence and Brockton one each. From malarial fevers, New York eight, Brooklyn three, Charleston one. From cerebro-spinal meningitis, New York six, District of Columbia, Nashville and Worcester one each. From erysipelas, New York two, Philadelphia, Brooklyn, Boston, Cambridge,

and Salem one each. From small-pox, New York and Brooklyn, two each. From puerperal fever, Philadelphia and Fall River one each.

In the 19 cities and greater towns of Massachusetts, with a population of 895,246 (population of the State 1,941,465) the total death-rate for the week was 20.74 against 22.02 and 22.61 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,245,000, for the week ending January 8th the death-rate was 2.65. Deaths reported 4,690: infants under one year of age 800; acute diseases of the respiratory organs (London), 731; measles 235; whooping-cough 81, scarlet fever 65, fever 47, diarrhoea 28, diphtheria 21.

The death-rates ranged from 40.6 in Plymouth to 15.7 in Sunderland; Birmingham 24.4; Blackburn 23.7; Hull 20.4; Leeds 24.0; Liverpool 28.8; London 26.3; Manchester 36.4; Newcastle-on-Tyne 33.2; Nottingham 18.3; Sheffield 21.4.

The meteorological record for the week ending January 22, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending Saturday, Jan. 22, 1887.	Barom- eter.	Thermometer.				Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 22, 1887, TO JANUARY 28, 1887.

MORRIS, EDWARD R., assistant surgeon. Granted leave of absence for one month, to take effect about March 10, 1887, with permission to absent for an extension of twenty days. S. O. 6, Division of the Pacific, January 19, 1887.

#### SOCIETY NOTICES.

**MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT.**—THE SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE will meet at 19 Boylston Place, on Wednesday, February 9th, at 7.45 o'clock. Papers: Dr. H. C. Haven will read a paper on "Infant Feeding," which was postponed from the November meeting. Dr. E. M. Buckingham will open the discussion. Dr. F. W. Stuart will report a case of "Thrombosis of the Left Vertebral Artery with Autopsy." Dr. W. N. Barnard will open the discussion. Dr. J. W. Farlow will present a series of five cases of "Large Visible Pulsating Artery on the Posterior Wall of the Pharynx."

ALBERT N. BLODGETT, M.D., Secretary.

F. I. KNIGHT, M.D., Chairman.

**BOSTON SOCIETY FOR MEDICAL OBSERVATION.**—A regular meeting of the Boston Society for Medical Observation will be held at the Medical Library, 19 Boylston Place, on Monday evening, February 7th, 1887, at eight o'clock. Readers: Dr. F. B. Harrington, "A Case of Osteo-Sarcoma of the Lower Jaw;" Dr. F. C. Shattuck, "Subsequent History of a Patient with an Abdominal Tumor diagnosed as Floating Spleen, in 1877."

CHARLES P. STRONG, M.D., Secretary.

**GYNÆCOLOGICAL SOCIETY OF BOSTON.**—The next meeting of the Gynecological Society of Boston will be held at No. 19 Boylston Place on Thursday, February 10th, 1887, at 4 o'clock, P. M. Communications: Dr. Apostoli's paper, entitled, "A New Method of Treatment of Chronic Metritis—and especially Endometritis—by the Intrauterine Chemical Galvano-caustic," will be read by Dr. Fox, of Lowell. A paper by Horatio R. Bigelow, M.D., of Leipzig, entitled, "The Truths of Nature demanding Similar Truths from Science and Art." Should time permit, the discussion of the subject, "Masturbation in the Female and the Advisability of Battley's Operation in Extreme Cases of Nymphomania," will be resumed; Dr. E. W. Cushing and Dr. W. S. Brown will open the discussion.

H. J. HARRIMAN, M.D., Secretary.

#### A PRIZE ESSAY ON HAY FEVER.

The Chairman of the Committee on Scientific Facts, of the United States Hay-Fever Association, asks leave to submit the following to the members, and to the Medical Fraternity, and to all who are interested, whether as sufferers or students of this increasing malady:

At its last meeting, September, 1886, at Bethlehem, N. H., the Association decided to offer a prize for the best essay from a competent source, preferably a physician, on some question relating to *Etiology*, or *Hay-Fever*. The amount is necessarily small; but, as the accepted Essay will be published in the Association's report, when the extent of its circulation, and the character of those whom it will reach shall be considered, it is thought that the successful treatise will give to its author a reputation worth the effort.

In order to carry out the above the following is announced officially:

(1) Subject of the Essay, Hay-Fever. (a) Its Pathology. (b) The predisposing, and the aggravating causes. (c) Advice to the sufferer.

(2) The Essay not to exceed four thousand words, and to be as practical and non-technical as possible.

(3) The manuscripts to be received at the office of SAMUEL LOCKWOOD, Freehold, New Jersey, not later than April 30, 1887.

(4) Each manuscript to have a Motto under the Title, and to be accompanied with a sealed letter containing said Motto, also the name and address of the author. These letters not to be opened until after the award is decided.

(5) The prize to be \$25. The accepted essay to be published immediately in the Association's annual report, one hundred copies to be given the author.

(6) The Committee of award: Samuel Lockwood, Chairman of Committee on Scientific Facts; Frank B. Fay, President U. S. H. F. A.; Charles C. Dawson, Secretary U. S. H. F. A.

Respectfully yours, SAMUEL LOCKWOOD,

Chairman of Committee on Scientific Facts.

FREEHOLD, N. J., January 15, 1887.

#### DEATHS.

Died at Princeton, Mass., January 28, 1887, Joseph Thomas Odiorne West, M.D., M.M.S.S., aged about sixty years.

Died in Walpole, Mass., January 29, 1887, Silas Emlin Stone, M.D., M.M.S.S., aged forty-eight years.

Died in Lawrence, Mass., January 31, 1886, Anthony Bernard Magee, M.D., M.M.S.S., aged thirty-eight years.

#### BOOKS AND PAMPHLETS RECEIVED.

Annual Report of the President and Treasurer of Harvard College. 1886-86.

Inebriate Maniacs. By T. D. Crothers, M.D., Superintendent of Walnut Lodge, Hartford, Ct. (Reprint.)

Twenty-Sixth Annual Report of the House of the Good Samaritan, McLean Street. For the Year ending January 1, 1887.

The Principles and Practice of Operative Surgery. By Stephen Smith, A.M., M.D., etc. New and Thoroughly Revised Edition, Illustrated with 1005 Woodcuts. Philadelphia: Lea Brothers & Co. 1887.

Clinical Observations on Endoscopy of the Male Urethra. By Hermann G. Klotz, M.D., Attending Surgeon to the Department for Skin Diseases and Venereal Diseases in the German Hospital and Dispensary, N. Y. (Reprint.)

Rhinology in the Past and of the Future. An Address delivered before the American Rhinological Association, on October 5, 1886, at St. Louis, Mo. By Carl H. Von Klein, A.M., M.D., of Dayton, Ohio. Chicago, 1886. (Reprint.)

Sterility. Management of the Secundines. By William H. Wathen, M.D., Professor of Obstetrics and Diseases of Women and Children in the Kentucky State Medical Society, etc. 1887. (Reprint.)

The National Dispensatory, containing the Natural History, Chemistry, Pharmacy, Actions and Uses of Medicine. Including those recognized in the Pharmacopias of the United States, Great Britain and Germany, with numerous references to the French Codex. By Alfred Stillé, M.D., LL.D., and John M. Malsek, Phar.D. Fourth edition, Revised and Improved, with 311 illustrations. Philadelphia: Henry C. Lea's Son & Co.

## Original Articles.

"IS THE DANGER FROM POST-PARTUM HÆMORRHAGE INCREASED BY THE USE OF ANÆSTHETICS DURING PARTURITION?"<sup>1</sup>

BY FORDYCE BARKER, M.D., LL.D., OF NEW YORK.

THE affirmative answer to the question which forms the title of this paper was one of the most effective arguments urged against the use of anæsthetics in midwifery, nearly forty years ago, by men of such obstetrical eminence as Tyler Smith, Robert Barnes and many others. It carried great weight, as it seemed obvious that an agent which paralyzed sensation, and if carried to its full effect, equally paralyzed voluntary motion, must inevitably arrest that muscular contractility which is the essential condition for preventing post-partum hæmorrhage.

The influence of this impression is seen in the fact that nearly all works on obstetrics, even by the most recent authors and many writers in medical journals, refer to the danger of anæsthetics in causing post-partum hæmorrhage. Barnes, for example, speaks of anæsthesia, induced by chloroform or ether, as among the most efficient causes of post-partum hæmorrhage. These warnings work for good in so far as they lead obstetricians to take those precautions, which I believe to be a duty in every case of labor, to prevent this appalling accident; for it is my firm conviction that no woman under the care of a watchful, prudent and competent obstetrician ever ought to die from post-partum hæmorrhage, due solely to uterine inertia or ataxy.

This paper will only refer to hæmorrhage from this cause, as no one will assume that anæsthetics can produce these local lesions which we all know sometimes cause terrific and even fatal hæmorrhage.

No one can doubt that either chloroform or ether may be given to an extent so far beyond anæsthesia as to induce profound narcosis; or that if the uterus be suddenly evacuated while in this condition, there would be a temporary paralysis of the organ, with a loss of power to contract and close the open mouths of the utero-placental vessels.

The real question is whether anæsthetics, properly administered, should be withheld from a woman in labor, when desirable to save her from unnecessary suffering on account of the danger of their causing post-partum hæmorrhage.

I may here say that I have long regarded chloroform as the safest and best anæsthetic in obstetrics, and that since 1850 I have used no other.

My reasons for this preference are briefly these:

*First.* Its odor is to most persons much more agreeable, and it is much less persistent. When sulphuric ether is used, it frequently at first produces more or less irritation of the fauces and bronchi, and an annoying cough or choking is excited. The effect of this is bad, both on the patient and on the surrounding friends. It excites apprehension which more or less tends to counteract the influence of the agent.

*Second.* The influence of chloroform is much more rapid, and a much less quantity of this agent is required than of the ether. We are thus saved, in a great majority of cases, the preliminary stage of excitement which the ether produces, and we are able to use the

chloroform for each recurring pain, the patient in the interval being comparatively free from the influence of the anæsthetic. Thus in the aggregate, not only is a much less quantity of the agent required, but the patient is exposed to the danger from the anæsthetic, if any danger there be, for a much shorter period of time.

*Third.* By chloroform we are able to regulate the degree to which we may desire to carry anæsthesia with a certainty and security that are not possible with the ether.

*Fourth.* The danger from anæsthesia by ether, where disease of the kidney exists, first pointed out by my friend Dr. Thomas Addis Emmet, and now confirmed by several observers, has not been noted by any one as resulting from the use of chloroform.

We all know that the great security against post-partum hæmorrhage lies in the efficient and permanent contraction of the uterus after delivery.

While we are constantly meeting in obstetrical literature with the statement that the danger of post-partum hæmorrhage is increased by the use of anæsthetics, I have never been able to find any statistical evidence in proof of the assertion. What is termed uterine inertia is often but another name for uterine exhaustion, and this must certainly be much less likely to occur when the nerve force and vital powers have been saved by the use of an anæsthetic.

This uterine exhaustion may be and often is the result of a prolonged labor, and while I am convinced that the effect of chloroform is often to prolong labor, I have not been satisfied that this apparent objection was not more than counterbalanced by the advantages obtained by its use, even where the use of the forceps has been made necessary from this cause.

But in a large majority of patients my experience would lead me to the conviction that the use of chloroform shortens the labor. I am certain that it does in all those cases where the pains are diminished or suspended by extreme sensitiveness and fear of pain—by vivid moral impressions of hysteria—or by pains resulting from the coincidence of some malady, either existing antecedent to, or appearing during labor, such as rheumatism of the uterus or other muscular tissues, or sharp pains in the back or abdomen distinct from the pains from uterine contractions, gripings in the intestines, or the cramps which are occasionally produced by the pressure of the child's head on the sacral nerves, and finally, in all those cases where inefficient uterine action results from loss of sleep and extreme exhaustion from a prolonged first stage, and in many cases where the labor is retarded by rigidity of the os uteri or perineum. Thus on the whole I am obliged to state my conviction that chloroform accelerates labor in a greater proportion of cases than it retards it.

I have attended a number of patients who, in previous labors have had their lives endangered by post-partum hæmorrhages and who were placed under my care for this reason. All these cases I have watched with the greatest anxiety, and have endeavored to see that they were in such a condition as would best prevent the occurrence of this accident after delivery. On questioning them or their intimate friends, or where practicable, their former medical attendant, I have learned that their previous labors have almost invariably been followed by great prostration, and that when labor was completed they were in a state of

<sup>1</sup> Read at the Medical Society of the State of New York, Albany, February 1, 1887.

almost extreme exhaustion. A peculiar idiosyncrasy or a former tendency to hæmorrhage or an extreme feebleness of the patient has been assigned as the reason why chloroform had not been given in former labors; the very reasons why I should consider this anæsthetic, properly and watchfully administered, as especially indicated. Such patients have generally remarked to me, when they have come out from the influence of the anæsthetic, "How different I am from what I ever was before, after confinement." They take nourishment and stimulants, if need be, and I then feel warranted in assuring them that all danger of "flooding" has passed, but I never leave them until I am certain of the fact. When I do leave, I give emphatic directions to the nurse, for close watching and minute instructions as to what she shall do if there be the least threatening of hæmorrhage.

Some years ago this subject came up for discussion incidentally before the American Gynecological Society,<sup>2</sup> in which one of my most valued friends, and certainly one of the most able writers on certain obstetrical subjects, expressed great surprise at statements of mine like those just made, for the previous winter I had been called to see a case in consultation with him on account of post-partum hæmorrhage which he regarded as due to the inhalation of chloroform. At the time, from the history then given, it was my conviction that the hæmorrhage was the result of a very inefficient and partial use of the anæsthetic, as the patient, a very nervous, excitable woman, was extremely intolerant of pain, and, in consequence, she never called to her aid the accessory muscles, and after several hours he was obliged to use the forceps. The hæmorrhage which followed was the result of uterine exhaustion, due partly to emotional causes, and partly to the fatigue of a prolonged labor. Three years after, by reason of the death of my friend, I attended this same patient in her second confinement. She was so sensitive to pain which bore no relation to the force of the uterine contractions, that early in the labor I gave her ten drops of Magendie's solution with the effect of quieting her, but regular labor pains did not follow.

She was extremely apprehensive of danger from the inhalation of chloroform. After watching her ineffective labor for some hours, I persuaded her to make only one full inspiration of chloroform to relieve the next pain. She was ready to make two inspirations with the next, and three with the next, and soon came under its full influence during the pains, but was perfectly conscious for a moment or two during the intervals; until with the return of a pain she would very impatiently call for the chloroform. After this the labor went on regularly and rapidly, so that the child was born within one hour after she commenced the inhalation of the chloroform, and the delivery was followed by perfect uterine contractions and no hæmorrhage. Her convalescence was in every respect most satisfactory.

In the discussion before alluded to, my friend expressed the opinion that danger of hæmorrhage did not follow the use of sulphuric ether. I have never seen hæmorrhage follow the use of either agent (I have never used ether in obstetric practice since 1850), but I should reason *à priori*, that an agent which paralyzed the nerves of the uterus, and thus prevented its permanent contraction, would be dangerous in

exact ratio with the continuousness of the effect, and that an agent from which the extent of the anæsthesia is perfectly under the control of the administrator, and the effect of which is intermittent, and which is only used during the time of pain, would be safer.

The danger of post-partum hæmorrhage in patients with cardiac disease is known to all. It seems to be almost accepted as an axiom with both the profession and the public that the inhalation of chloroform is dangerous for any women with "disease of the heart." For more than thirty years I have been convinced that this opinion is quite erroneous, and I have so taught in my lectures and in former writings.

In March, 1853, I was called to see the wife of a physician in this city in her fifth labor. I had seen her once before, the latter part of the previous December, with the late Professor Chandler R. Gilman, to decide as to the propriety of the induction of premature labor, as she was suffering from severe cardiac troubles.

She had been repeatedly examined by Dr. Alonzo Clark, whose diagnosis was, great dilatation of the left ventricle and mitral insufficiency. We were then in full accord that the induction of premature labor would be unsafe. When labor came on, I was sent for, as Dr. Gilman was ill. When I saw her, she had been in the second stage of labor, as her husband said, about one hour. The first stage had been nearly four hours, unattended by any symptoms to cause grave anxiety, but when the expulsive pains began, her condition became rapidly bad. Each pain, which recurred every six minutes, caused faintness, nausea, and slight vomiting, but the pains were much more severe in the chest than in the uterus. Her appearance was appalling, the countenance was extremely pallid, the lips and fingers were cyanosed, the face was covered with large drops of perspiration, and the pulse very weak and irregular. The os was nearly dilated, very soft and yielding, the membranes protruding, but the pains were ineffective. After watching her for a few moments, I regarded her condition as perfectly hopeless, and proposed chloroform, solely in my own mind, with the hope of euthanasia. Her husband would not consent to this, making the objection that she could not bear an anæsthetic, as she had once inhaled ether to have a couple of teeth extracted, with very dangerous results. I then gave her five drops of Magendie's solution of morphine, which was followed for a time by some improvement. But soon after her condition became as bad as before, until I could not bear to witness her suffering any longer, and avowed my intention of leaving, as I could be of no service. Her husband begged me to stay, adding, "Do what you think best, and God help you."

The few moments that we had to wait before the chloroform could be obtained, seemed to me so many hours, which I passed in trying to get her to swallow some brandy and water, to which she had a great aversion, and in explaining to her exactly *how* I wished her to inhale the chloroform, I began by giving her a few whiffs first, as an impending pain was apparent, gradually increasing the amount until she became unconscious during the pains. She was always conscious sometime during the interval after each pain. After a short time, a wonderful change was apparent, her pulse became regular and stronger, while her husband, who frequently counted it, said that it never

<sup>2</sup> Transactions, Vol. VII, p. 78.

exceeded 96 a minute, while before my arrival it had been 140 in the intervals, but could not be counted during the pains. Her countenance improved in color and assumed a most placid, contented expression.

During the pains there was no voluntary assistance on the part of the patient, and but slight aid from the accessory muscles. After she had been taking the chloroform an hour, the membranes ruptured, and, finding the head low down in the pelvic cavity, the position favorable, and the soft parts yielding, I said to the husband, "What is the use of letting her suffer more fatigue? The forceps can be applied with great ease, and may shorten the labor two or three hours." It was applied without changing her position in the bed, and in a few minutes she was delivered of a living girl weighing six pounds and a half. She made a very good convalescence.

In January, 1856, I again attended this lady in confinement. For the three months previous, I had seen her often and had endeavored to lessen the labor of the heart by improving the character of the blood which it circulates by such medicines as the tincture of the chloride of iron, the chlorate of potassium and digitalis. The labor was short and comparatively easy, under chloroform and delivery by the forceps. She outlived her husband three years, but died in July, 1860, from Bright's disease and her cardiac trouble.

Since this case I have seen several others, in which labor was dangerously complicated with heart troubles and which terminated favorably as I think, solely from the use of chloroform.

As far as I know, these views which I have long taught, had been advocated by no author, until the publication of the valuable work by Dr. Angus MacDonald, of Edinburgh, in 1878. His explanation of how the uterine contractions of the second stage, where heart trouble exists, cause the dangerous symptoms of violent palpitation, dyspnoea, syncope, etc., is most satisfactory to my mind.

I find the following sentences in the most recent work on obstetrics, a most interesting and valuable text-book by Dr. Parvin.<sup>2</sup> "Vergely, quoted by Dutertre, states that cardiac diseases do not forbid the use of an anæsthetic in labor and chloroform acts as a sedative in these affections, and may be given prudently. Barr believes that obstetric anæsthesia has a beneficial sedative action upon the heart."

An interesting paper on this subject, by Dr. J. L. Owen, appeared in the *New Orleans Medical and Surgical Journal*, in 1881.

There are so many important papers to be read before the Society that it would be wrong for me to occupy its time longer. I will therefore close with a statement of my personal experience in the use of chloroform in parturition.

During the past thirty-seven years I have rarely attended a woman in confinement without the use of chloroform, never where she has suffered considerable pain. Having thus used it in several thousand cases, I unhesitatingly assert that not in a single case have I ever found cause to regret its use.

In addition to my own experience, I have carefully watched for all that has been published on this subject, and I am fully in accord with an eminent authority on obstetric anæsthesia, Dr. J. C. Reeve, of Day-

ton, Ohio, in his assertion that<sup>1</sup> "the most rigid scrutiny, inspired by hostility, has failed to show that, when judiciously used, it exerts any injurious influence on the mother or child."

"Chloroform has been used in natural labor many hundred thousands of times, yet but a single case of death is on record when it was administered by a competent medical man, and of this there is lack of post-mortem confirmation." I will add that in this case the death was preceded by a convulsion.

In my private practice I have never had but one case of post-partum hæmorrhage, and in this, no anæsthetic had been used, as the child was born within five minutes after I entered the room, before I had time to make any examination, and a terrific flooding followed.

## RECENT PROGRESS IN LEGAL MEDICINE.<sup>1</sup>

BY F. W. DRAPER, M.D.

### ON DEATH BY HANGING.<sup>2</sup>

Dr. Pellereau reports his observations on death by hanging and on the anatomical appearances which result therefrom as he has noted them in fifty-six cases, suicidal and judicial, in the course of his official duty as jail-physician at Port Louis in the Mauritius Islands. Judicial executions are managed there as in England, by means of a drop of eight feet through a trap, the knot being placed under the chin of the condemned. When the drop occurs, the criminal makes no articulate sound; there is, at first, absolute immobility of very short duration during which no pulse is felt and no heart-beat is perceptible. Then follows a tetanic rigidity of the whole body, succeeded at once by energetic spasms. Loss of consciousness is evidently instantaneous, because in every case there is a complete dislocation of the atlas upon the axis. The convulsive movements are never wanting and they would be more conspicuous if the elbows and knees were free and not pinioned. Coincidentally with the convulsions, one hears a rattling sound produced by the movements of the tongue and of the respiratory muscles. Saliva in abundance, more or less blood-stained, escapes from the mouth and oozes through the black cap which covers the criminal's head. The bladder and rectum sometimes expel their contents meanwhile. These various phenomena may be divided into three well-marked periods: a period of immobility, one of tetanic rigidity and one of clonic spasms. They last altogether from two to three minutes,—not more than five minutes at the longest. Then everything relapses into the most complete inertia, and it is impossible to provoke the least reflex action. The author does not credit the notion that erotic sensations are experienced.

The position in which the bodies of suspended suicides are found is almost always vertical; often the feet rest on the floor or ground, more rarely the knees are bent so as to take the weight of the body, but the horizontal position has not occurred in the writer's experience. The head is most frequently found bent forward, the chin resting on the breast; the position depends greatly on the place of the knot

<sup>1</sup> Concluded from page 113.

<sup>2</sup> *Annales d'Hygiène Publique et de Médecine Légale*, August, 1886, page 108.

<sup>4</sup> Wood's Reference Handbook of the Medical Sciences Anæsthetics page 103.

and on the number of turns of the cord about the neck. Cadaveric rigidity appears late, develops slowly and continues long. Animal heat is retained to an unusual degree. The countenance is sometimes calm and pale, sometimes swollen and livid with the eyes injected and prominent; the pupils are generally dilated. Ophthalmoscopic examination of the interior of the eye gives no results worthy of note. The tongue is often in its normal position behind the teeth; when it is protruded it is more or less swollen, dry and blackish, with fissures at its edges and tip. The escape of saliva from the mouth is essentially a vital act and is an important sign of death by hanging. The lower extremities are more or less livid and petechial spots are observed which, on section, are found to contain coagulated blood, thus indicating that the suspension was during life. The emission of spermatic fluid is not to be regarded as pathognomonic.

The neck invariably shows a groove made by the cord, and, except in judicial hangings, it is always deepest in front. The color of the furrow is uniformly red or brownish, according to the complexion of the deceased. Generally, there is neither excoriation nor ecchymosis in its course. Its direction is always oblique. Its situation is above the larynx. Its depth is determined by the duration of the suspension after death. Its diameter may be a little less than that of the cord.

Among the internal appearances, the author noted the following: In exceptional instances, one finds a small number of punctate ecchymoses under the skin of the face and neck, in the subcutaneous connective tissue and in the deeper structures; they are most marked in judicial executions. In the writer's experience, subconjunctival ecchymoses and fracture of the laryngeal cartilages were not present. Immediately after the suspension, if the body is cut down at once, the subcutaneous and deep tissues of the neck under the course of the cord are without a trace of depression; later there is a slight groove corresponding with the external furrow. In the author's cases, the intima of the carotids always escaped injury. The blood was generally black and fluid. The larynx often contained froth more or less blood-stained; the presence of morsels of food in the larynx is regarded as an important sign of suspension during life. The lungs were usually increased in volume; they were of a uniform red color and sometimes presented, either on their surface or in their substance, small, dark apoplectic nodules; punctate ecchymoses were not observed; at the base and edges were limited areas of superficial emphysema. The heart was nearly always found firmly contracted on its left side; its right cavities were distended with blood. In rare cases, there were punctate ecchymoses along the coronary veins. The liver sometimes presented hemorrhagic nodules in its substance. The small intestines were always deeply reddened. The stomach was oftenest found pale.

In judicial executions, the tissues in the vicinity of the atlas-axoid articulation were found considerably contused, and almost always, coagula of dark blood lay around the two bones. The ligaments of this articulation were ruptured, thus permitting complete luxation of the atlas upon the axis, and leaving a space between the two vertebrae sufficient to admit the finger. There was no fracture of either bone. The articulation of the atlas with the occiput was unin-

jured. The medulla suffered more or less bruising and tearing by the displacement of the atlas, and sometimes the lesion was so extensive that nothing but *débris* of nerve-elements remained, the organ being reduced to a pulp.

#### HUMAN FOOT-PRINTS.<sup>2</sup>

Upon the occasion of a murder, near the body of the victim of which were found, on the floor, seven impressions of a naked and bloody human foot, Dr. Masson made a special study of foot-prints, to settle the question whether the marks discovered were made by one and the same foot, and so by one person only. He found that the same foot would give foot-prints with very different dimensions, according as it was used in standing or walking, corresponding with the two essential functions of the foot, as an organ of locomotion and of support. In walking, there are two clearly-defined motions: The first, in which the weight of the body comes upon the heel, the forward part of the foot acting simply to maintain equilibrium; the second, in which the weight bears wholly upon the toes and the metatarsal articulations. In the second part of the motion of walking, the foot is lengthened from nine to twenty-three millimeters. The height of the plantar arch, while differing in different individuals, varies but slightly in the same foot in different positions; it is lessened a little in the act of walking. An added weight of twenty kilogrammes carried by the subject of the experiment does not modify materially the shape and size of the foot-prints made in walking.

It appears to the author impossible that two human foot-prints should closely resemble each other unless the same foot has made them. The impression made by a foot discloses such clear characteristics; the distinctive marks under differing conditions are so numerous; the foot-prints of the same foot are so alike under dissimilar circumstances, that an attentive expert, having good foot-prints to study, ought to arrive at clear and precise conclusions. The toes, the great toe especially, leave marks that should be examined attentively; these, and the outline of the digito-plantar depression, the line which defines the plantar arch, are the data for a diagnosis.

The author's conclusions are:

- (1) The dimensions and the shape of foot-prints made by the same foot vary with the attitudes taken.
- (2) The two extreme and characteristic types are represented by impressions made by the foot in walking and in standing.
- (3) The expert called to study the matter of foot-prints should always take impressions of the foot of the accused in the act of standing and of walking, and should compare only those which correspond with the same attitude.
- (4) In connection with the measurements made, one should always consider the points which throw light upon the individual characteristics of the foot.

#### THE MEDICO-LEGAL SIGNIFICANCE OF HÆMATOMA OF THE STERNO-MASTOID IN NEW-BORN CHILDREN.

Küstner<sup>3</sup> discusses the mode of origin of hæmatomata in the sterno-mastoid muscles of new-born children, and combats the view that they are always due to excessive traction of the neck. He relates a case of labor with breech presentation, no assistance of any kind being

<sup>2</sup> *Annales d'Hygiène et de Médecine Légale*, October, 1886, p. 226.  
<sup>3</sup> *Centralblatt f. Gynäkologie*, No. 2, 1886; *Amer. Jour. of Med. Sciences*, July, 1886, p. 292.

afforded; yet a hematoma appeared in the left sterno-mastoid, thus suggesting the inference that the accident may attend a perfectly normal labor.

Kistner also records some experiments made on still-born fetuses, in which a row of pegs was inserted into the sterno-mastoid, and the neck was then stretched and rotated in various directions. He found that neither lateral flexion nor stretching of the neck had much effect upon the sterno-mastoid, the pegs showing no separation; but torsion of the neck had a decided effect on the muscle, especially when the face was twisted toward the side under observation. He believes that a similar movement during labor is a cause of hematomata, for torsions of the neck are well known to be of frequent occurrence even in the ordinary mechanism of parturition.

The following conclusions are reached by the author: (1) Hematoma of the sterno-mastoid is caused not by stretching or extension, but by twisting of the neck.

(2) Since the neck may be twisted even in spontaneous delivery, a hematoma may arise in simple cases, both of vertex and breech presentations.

(3) The occurrence of a hematoma, therefore, does not prove that criminal or instrumental violence has been resorted to.

### Clinical Memorandum.

#### POISONOUS ARSENICAL WALL-PAPERS.<sup>1</sup>

BY JAMES R. CHADWICK, M.D.

In the presence of so many chemical experts and learned general practitioners it would be presumptuous in me to attempt to treat this subject systematically or exhaustively. Moreover, my purpose in opening this discussion is to present, by fresh instances, to the public and profession, the dangers to which every citizen of this Commonwealth is exposed by the manufacture and sale of papers for our walls so charged with arsenic as to produce characteristic symptoms of the poisoning by that mineral in the persons occupying the rooms thus papered. The Legislature of this State last winter failed to pass a bill prohibiting the use of arsenic in the coloring of wall-papers, so that the only means by which we can save ourselves from this poison, is to disseminate so full an appreciation of our danger throughout the community as to cause every individual to protect himself and his family. This end can only be attained by the publication, by every one who has suffered, of the exact circumstances attending his experience, together with the names of the dealers retailing the papers and the chemists who have analyzed them. This I shall aim to do without animosity to any individual, but with the single purpose of making every one feel more keenly than they now appear to do the responsibility for the lives and health of our wives and our children.

In September, 1885, Messrs. J. F. Bumstead & Co. put upon my nursery and one sleeping-room new papers, which they assured me had been analyzed and pronounced free from arsenic. In the nursery slept a boy of four years and a nurse, in the chamber slept a girl of thirteen, in a third room, not then re-papered, slept two other children. All the children passed several hours of every day in the nursery. During

the winter of 1885-86, the boy and nurse remained in good health, the girl of fourteen, however, suffered much, for the first time in her life, from dyspepsia, colicky pains and headaches; the younger of the two girls had many attacks of palpitation of the heart, lost color and strength; the other girl kept in good health. The symptoms in the two affected girls yielded somewhat, but never fully, to treatment. During the summer of 1886 they regained their health and strength at Mt. Desert; within a month of their return to their home many of the old symptoms reappeared. About the first of December the attacks of colicky pains became more severe and frequent in the two affected girls and were attended by vomiting and diarrhoea.

My attention was then aroused and I set about to discover a common cause for all these similar symptoms. Having suffered severely in past years from the poisoning of my family by arsenic, I naturally thought of that possibility and sent samples of the papers most recently put upon the walls (nursery and small chamber) to Prof. E. S. Wood for analysis, and received the following reply:

"BOSTON, December 10, 1886.  
"The enclosed paper (from the nursery) is very arsenical. I should advise its removal. The other was all right, non-arsenical."  
EDWARD S. WOOD."

I was naturally in a state of great indignation that, despite my care, I should have had put upon the wall of my nursery a paper which contained a dangerous amount of arsenic. I wrote at once to J. F. Bumstead & Co., asking the name of the chemist who had made the analysis for them. The reply was as follows:

"BOSTON, December 13, 1886.  
"DR. JAMES R. CHADWICK,  
Dear Sir,—The paper about which you enquire was analyzed by Prof. S. P. Sharpley and by him pronounced "free from arsenic."  
Yours truly,  
"J. F. BUMSTEAD & Co., per HENRY."

It happened that a week previous to this correspondence my wife had taken a friend to the store of J. F. Bumstead & Co., where he had purchased several hundred dollars' worth of papers for a newly-erected house in California. On the same evening I questioned my wife closely as to whether she had been careful to select only papers that were free from arsenic. She said she had insisted upon that point with Mr. Bumstead himself, and had been told that only those papers would be shown her which had been analyzed and pronounced to be free from arsenic. I asked if she had inquired who their chemist was, to which she replied that Mr. Bumstead had told her that their chemist was a Professor Hills. As I knew that this could only be Prof. Wm. B. Hills, of the Harvard Medical School, I felt assured that the papers were safe. A week later, however, on discovering that my own paper was arsenical, and feeling responsible for my friend in California, I went to the store of Bumstead & Co., and demanded to see the reports of Professor Hills upon the fourteen papers selected by my friend. I was told to call the next day when they would be shown me. I did so, and then found that all the papers had been (owing to a misunderstanding) sent to Professor Hills for analysis since my visit the previous day. One of them had been pronounced by him to contain "considerable arsenic," and another a "small amount," both being regarded as more or less dangerous to health. The others were all practically free from arsenic. On asking upon

<sup>1</sup> Read before the Section for Clinical Medicine, Pathology and Hygiene, of the Suffolk District Medical Society, January 12th, 1887.

whose certificates the two first mentioned papers had been supplied as "free from arsenic" I was shown the certificates of Prof. S. P. Sharples.

In order to confirm the presence of arsenic in dangerous amount in the three papers about which the reports were conflicting, I have since had each of them analyzed independently by Prof. E. S. Wood, Prof. W. B. Hills, and Dr. Chas. Harrington, all of the Harvard Medical School, with the result of perfect concurrence as to finding arsenic in dangerous amount.

But little comment is needed on this recital of facts. It is, however, but just to Mr. Bumstead to say that I fully exonerate him from any intent to mislead my wife with regard to the analyst of the papers supplied to my friend. His statement that Professor Hills is now his analyst is true, yet I think I am right in pointing out to him that his reply was so framed as to be misleading, because the papers he was offering for sale had many of them, as is manifest, been analyzed in previous years by other chemists.

I may say, in conclusion, that it makes no difference whether the symptoms manifested by two of my children be adjudged by those present as due to arsenic or not; if I demand papers free from arsenic I ought to be able to obtain them. My own belief is that the symptoms are attributable to that cause, and that the exemption of the nurse and two other children, though in two instances more constantly exposed to the influence, was attributable to the fact that they were less susceptible to the poisonous effects of arsenic. I pass around samples of the papers with the arsenical mirrors obtained by the Berzelius-Marsh test.

I should add that the two affected children have had no symptoms since the paper in my nursery was removed a month ago.

### Reports of Societies.

#### MASSACHUSETTS MEDICAL SOCIETY. SUFFOLK DISTRICT. SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE.

ALBERT N. BLODGETT, M.D., SECRETARY.

JANUARY 12, 1887. The meeting was called to order at 8 o'clock by DR. F. I. KNIGHT, Chairman. On motion, the reading of the records of the last meeting was omitted. The Chairman announced the subject for the present meeting to be a debate upon the danger to the public from

#### ARSENICAL WALL-PAPERS,

and called upon Dr. J. R. Chadwick to open the discussion.

DR. CHADWICK, in response, presented an interesting and vivid account of the occurrence of arsenical poisoning in his own family<sup>1</sup> on several distinct occasions, and spoke of the uncertainty which exists in relation to the presence of arsenic in wall-papers, even when the dealer presents the certificate of a chemist as evidence that the papers are free from this dangerous substance. At the close of his remarks, Dr. Chadwick offered the following resolution:

*Resolved*, That it is the opinion of this meeting that the clinical evidence already adduced in this and other countries establishes beyond doubt the fact that arseni-

cal wall-papers will, in many instances, produce symptoms of poisoning by arsenic in persons occupying the rooms whose walls are covered by such papers.

The resolution was seconded, and was then declared open for discussion.

The Chairman introduced MR. N. W. BUMSTEAD, the well-known paper-dealer, who was invited to address the meeting. Mr. Bumstead responded by saying that he did not desire to occupy the time of the members to any great extent. In all large establishments there are many persons employed, and the facts in regard to the purchase of paper by Dr. Chadwick are that Mr. Bumstead did not personally exhibit the papers, but a salesman in the service of the firm was the person who made the transaction. The statement was made to the purchasers that no papers would be shown except such as had been pronounced by chemists of repute to be free from arsenic, and such was the fact.

It is desirable that the position of the paper-dealers should be placed before the profession in a more correct light than is at present the case. The efforts and desires of the dealers are directed toward the elimination of all articles from the colors and other processes of manufacture of wall-papers supposed to be dangerous, and the substitution thereof of equally useful, but unobjectionable methods of manufacture. Personally, the paper-dealers do not place credence in very many of the alarming reports which are, from time to time, circulated in relation to the occurrence of dangerous interference with health from the action of the colors used in wall-papers. It is both a mistake and an injustice to suppose that the dealers do not take pains to have their wares examined in relation to their safety. Messrs. Bumstead & Co. have had four different chemists in their service during the last twelve years. The intention was to exclude objectionable papers from the business. About two or three years ago, an agreement was made between some of the wall-paper manufacturers and Mr. Bumstead that they should take back all arsenical papers. After a trial, the manufacturers declined to continue the arrangement on account of the great frequency of rejected papers; but lately they again consented to receive all papers returned to them which contain more than a trifling amount, called a trace, of arsenic. A portion of the present disturbance in regard to arsenical papers arises from the fact that many of the papers now examined are such as were manufactured some years ago, and some of the papers have been for years on the walls of inhabited rooms, where they have produced no appreciable symptoms of poisoning until the present excitement was inaugurated. The occurrence of arsenic in these accidental ways should not be looked upon as fairly representing the paper manufacture at the present time.

DR. C. E. STEDMAN said that he had little to offer to the remarks of those who had preceded him. Some years ago he purchased wall-paper from a firm now gone out of trade, and it was put on the walls of his house. For two or three years the occupant of that room was continually ill, the symptoms being a persistent diarrhoea, with colicky pains, etc.; and finally, a severe form of eczema supervened, for which various forms of treatment were ineffectually tried, and at length the patient was placed under the care of Dr. Wigglesworth, of this Society. At a later period, Dr. Stedman for a time occupied the room in question as

<sup>1</sup> See page 129 of the Journal.

a sleeping-room for himself, and soon became ill, suffering from an obscure form of ocular disease, for which he consulted Dr. Wadsworth, of this Society. After some time, Dr. Wadsworth suggested the possibility of arsenical poisoning, and that the wall-paper might be the source of the trouble, when the paper was subjected to chemical analysis, and was found to contain a large amount of arsenic. The paper was at once removed from the walls, and a paper substituted which contained no arsenic, since which time there has been no recurrence of the symptoms of poisoning, or, in fact, any other signs of impairment of health in any member of the family.

PROF. D. G. LYON, of Cambridge, was called upon by the Chairman, and said that on the 19th of January last he caused the publication of a long account of the troubles which had occurred in his house and family, for which, in his mind, there existed no cause, except the arsenical paper on the walls of his house. His family consisted of three members, Mrs. Lyon, himself, and another instructor in the University. They were all affected by a variety of distressing symptoms, one of which was persistent insomnia. It was almost impossible for any member of the family to sleep at all. In addition to this, a common symptom was pain in the head, palpitation, general debility, etc., which proved refractory to all methods of treatment for its relief. Physicians were called, but were not able to alleviate the distressing conditions, which now began to cause serious alarm. Professor Sanger was consulted, and he examined the furnace, sewers, etc., but being unable to locate the trouble in either of these parts of the household apparatus, he at length suggested the possibility of the wall-paper being the agent which had operated so disastrously upon the family. This was immediately submitted to chemical analysis, and yielded a large amount of arsenic.

"I had recently read," continued the speaker, "the admirable paper of Professor Wood on the subject of 'Poisoning from Wall-Papers,' and observed that the symptoms which he there recorded were almost identical with those experienced by the members of my family, from circumstances similar to those surrounding the cases mentioned in the article by Professor Wood.

"Four rooms were covered with paper containing extremely large quantities of arsenic, as determined by chemical analysis. The papers were at once removed, and the walls re-covered with papers which were free from arsenic, and the immediate result was the entire and rapid disappearance of all the symptoms of disease which had so long existed, and which had thus far been quite unaffected by any form of remedial treatment.

"Chemical examination of the wall-papers of different dealers, a year ago, showed that more than fifty per cent. of the papers in the stock of the Boston dealers contained a much larger amount of arsenic than the bill at that time presented before the Legislature asked for. The manufacturers claim that a law which should limit the amount of arsenic contained in wall-papers would seriously affect their trade, and that certain forms of papers cannot be produced without the aid of arsenic, or, at least, without the use of substances in which arsenic may exist. Within a stone's throw of my house in Cambridge are families which have suffered more than my family did. In all parts of this Commonwealth, cases of poisoning from the

use of arsenical papers are known, and the appeal of all these people is only for a law by which they may be protected from a danger which they have no means of recognizing for themselves. Those people who bought wall-papers in Massachusetts, and especially in Boston, a year ago, assumed a serious risk to the health of their families, from the almost universal presence of arsenic in the wall-papers of that time. I could report more than forty families thus affected from this cause."

PROF. E. B. YOUNG said that he has never appeared before the legislature, nor has he ever published anything in the papers in relation to the dangers from arsenic. He has been a long but silent sufferer from the effects of poisoning by arsenic in wall-papers in his house. In his case the symptoms were a palpebral inflammation of both eyes with continual lassitude, weakness, etc. His daughter, formerly strong and robust, became weak, languid and feeble. Professor Young himself was not well. The occurrence of such an amount of sickness in his family without adequate cause made him anxious. He employed men to overhaul the sewers of the house, but the drainage was found in good condition. At this time Professor Lyon suggested the possibility of arsenic as the cause of their discomforts and the papers of the house were at once subjected to analysis. In a light blue paper arsenic was found to the extent of 4.97 grains to the square yard. In some English cretonne used for upholstery, there was discovered 4.00 grains of arsenic to the square yard. This had been in service for some time, and had begun to wear, and, with the destruction of the texture of the fabric, the arsenic had become more readily disseminated. The paper of another room contained  $\frac{1}{3}$  grain to the square yard. Professor Young's daughter was much troubled by an affection of the throat, for which she was placed under the care of Dr. Knight, the Chairman of this meeting, and, as she did not improve, she was sent to Dublin, where she began to get better. After a time the urine was examined, and was found to contain arsenic. After the restoration of the house, the daughter's health was again restored, and a letter from her physician who has had the urine again examined, contains the report, "no trace of arsenic in the urine at present." In the dining-room of the house arsenic was discovered in the paper. The result of all this has been to cause a large outlay in money, as well as a great amount of anxiety through a long time; and we feel that we have the right to demand legal protection from this known and recognized source of danger to our families. Nobody claims that arsenic causes *all* the illness in families, but it undoubtedly causes *some* of it. Nobody thinks arsenic does any good in the papers, and it is certainly better out of the way, than to be thus a constant source of possible danger. Another case was that of the daughter of a clergyman of Jamaica Plain, who was ill from an obscure cause, but in whose house the papers were found to contain arsenic. She was quite well soon after the old papers were replaced with non-arsenical ones. Another case was that of an entire family in Cambridge, the name of which would attract attention as belonging to the higher walks of literature, in which there was unmistakable poisoning. Another instance occurred in Milton, where there is a house, one room of which possessed the peculiarity that every person who occupied this particular apartment was certain to

become ill. Each member of the family had in turn occupied this chamber, and each in turn had been similarly affected. The paper from the walls of this dreaded apartment was analyzed and contained a very dangerous quantity of arsenic. An Episcopal clergyman and his wife were both poisoned by arsenical paper not long since. The husband was confined to the bed in the room, and grew worse, while the wife, who was not so ill, but could pass a good portion of the time out of the room, was not so seriously affected. Another well-marked case occurred in Waltham. Perhaps the most amusing fact, however, is that Professor Sanger was himself poisoned last summer at the seashore. He was assigned a room which was papered with highly arsenical paper, and was soon made ill by it. Professor Young then passed specimens of the papers removed from his house, to the members of the Society, remarking that there is absolutely no way in which arsenical papers can be detected excepting by chemical analysis, and that therefore the most careful selection is no protection against this danger.

PROF. WM. B. HILLS, of Harvard University, was then announced, and spoke as follows: It has fallen to me to examine as many papers probably, as to any one in this city, during the past few years, and I now examine for two of the most prominent paper houses in the State. From my experience I am convinced that the present alarm concerning arsenical poisoning from this source is unnecessarily great. The results of analysis during the past few years show this fact conclusively, as the following figures will prove. During the period from 1879 to 1883 the percentage of arsenical papers was from fifty-four to sixty-five per cent. of all papers examined. In 1884 the percentage had fallen to forty-seven per cent. arsenical.

In the first series of figures, those from 1879 to 1883, from thirty-one to thirty-five per cent. of the papers were strongly, or dangerously arsenical. In the second series of figures, the proportion of strongly arsenical papers had fallen to twenty-two per cent. In 1886 there was a large decrease in the arsenical papers, only thirty-three per cent. of all papers examined containing any traces of arsenic. Only thirteen per cent. of these papers contained anything more than a trace of arsenic. These figures are the more startling on account of the extreme delicacy of the Marsh-Berzelius test which was employed in 1886 only; and it appears that the matter is slowly settling itself by the common efforts of the manufacturers and the trade toward satisfying the demand of the public that papers shall be made without the use of dangerous substances. It has been stated in this meeting that all papers are at present still strongly arsenical. This statement is not in accordance with my experience. Most of the papers taken from the walls of rooms are such as were manufactured some years ago, and may naturally be different in chemical composition from the papers made to-day. The fact is that papers now manufactured do not contain a dangerous amount of arsenic. I do not think that it is desirable to appeal to the legislature until we know definitely the present state of the case, and until we know the limit which it is safe to establish in relation to the accidental presence of small amounts of arsenic in the papers. A law to prevent the sale of "Rough on Rats" would save more lives than a law to prohibit the sale of wall-papers containing a trace of arsenic.

DR. H. J. BARNES asked what reason exists for the use of arsenic at all in the manufacture of wall-papers?

PROFESSOR HILLS replied that there is no reason for its use. It is not used intentionally, but exists as an adulteration in some of the pigments employed in the preparation of the paper. It is an impurity in certain of the mineral pigments which have been employed in the manufacture of former papers. Manufacturers are now trying to keep the arsenic out of their colors.

DR. EDWARD WIGGLESWORTH said that he had but little to add to what had been said in relation to the dangers from arsenical papers. He has suffered in his own family of four persons, from this cause. The symptoms were not alike in all, but were clearly traceable to the papers on the walls. A symptom possibly due to the elimination of arsenic from the system and not mentioned by those who had preceded him, was a frequent and violent desire to urinate, with a burning at the neck of the bladder, which ceased as soon as the urine was passed. There was no kidney trouble, no affection of the bladder nor urethra, nor any other condition to account for the distress which was present. His little boy occupied a newly-papered room, and was soon affected with conjunctivitis, coryza, anemia, anorexia, etc. The paper was analyzed and found to be arsenical. His little girl next showed the same symptoms. Dr. Wigglesworth stated that both he and his wife are still ill from the effects of poisoning, and the papers were found to contain from twenty to forty times the amount of arsenic which has been considered the limit of safety. When the symptoms of poisoning first became evident the cause was not recognized, and a journey to the South was made with the result that all symptoms of disease entirely disappeared. On returning, however, the original disturbances again appeared in their former intensity. The paper was removed, and replaced by non-arsenical paper, and the family is now on the way to recovery.

Dr. Wigglesworth next alluded to cases of eczema which had been found to be due to arsenic. A child had been under the best of care before, and nothing in the shape of attention could have been rendered that had not been most conscientiously carried out. When placed under the care of Dr. Wigglesworth, he at once decided that there must be some unsuspected cause for the disease. He went to the house of the patient, who was a dispensary case, and examined the plumbing with great care, and also inspected the premises in other directions. He at length decided to have the wall-paper examined, and it was found to contain arsenic in large amount. The child was removed to another room, and soon became better, but was not well. Upon removing to another house, however, there was complete recovery from all symptoms of disease. The daughter of a medical friend was seriously ill, with symptoms which would not yield to treatment. The paper on the walls was examined and was found to be loaded with arsenic. In the house of a relative is one room which seems to be a source of disease to all who inhabit the apartment. It has proved nearly fatal to two persons, and many more have been ill from occupying it. The cause was not suspected until the paper was examined and was found to contain a very large amount of arsenic.

DR. J. W. HARLOW, of Woburn, was then called

upon by the chairman, and stated that he would attempt to give a report for the Senate, as this matter was developed last year, at the hearing before that body. He would not attempt to speak upon the subject in any other way in the presence of this distinguished company, and all that he intended to say would be directed toward the legislative side of the question. The percentage which was proposed as the limit of safety in papers, was one-fifth of a grain in the square yard. We supposed that this would be sufficiently liberal for all persons, but the bill was not carried through. It seems to me that the physicians are now beginning at the beginning of the matter, and are working in the proper way to succeed in the proposed attempt to secure legislation on this important subject. At the hearing before the Committee from the legislature there was not that sequence of cause and effect, that close relation of the cause to the effect, which has characterized this meeting, and which physicians can so clearly establish, and which is the greatest element of success in an undertaking of this kind. The revelations which were made at the hearing at the State House, last year, were sometimes of a most unexpected and startling character. Some of the members were made to believe that while in Cambridge, Boston and possibly a few other obscure places, arsenic might occasionally be the cause of poisonous symptoms, when contained in large amounts in wall-papers, yet this same arsenic was not poisonous in New York. One gentleman thought that there was no more truth in the theory of arsenical poisoning from this source than there was in the old Salem witchcraft. The only way, and surely the best way, to succeed in the effort to secure a protection from this danger through any action on the part of the Legislature, is by agitation of the matter. Professor Hills states that there is already a notable decrease in the amount of this substance contained in wall-papers ever since the attempt to secure a law a year ago. There is one point in which there is much misapprehension in this whole matter. The claim is advanced that such legislative action as is asked for will have a tendency to oppress a great manufacturing industry. The fact is, that the manufacture of wall-papers is not an industry of this State. By far the larger part of the wall-papers used in Massachusetts are manufactured in New York. I believe that it is essential that a protective law should be passed in this State, which shall establish the limit to which arsenic may exist in wall-papers without being considered dangerous to health. The bill should specify the amount per square yard which the paper may contain without being considered injurious to the health of occupants of the rooms covered with the papers. The bill as heretofore presented was not broad enough to suit some of the advocates of a bill, and it was afterward extended so as to include toys, textile fabrics, candies, etc., which were claimed to constitute a much more threatening danger than that from wall-papers. The law which is asked for should be so drawn as to include all forms of textile and other fabrics, and all domestic appliances and all articles coming under the head of toys, etc., which are so largely distributed among children, and are a source of constant peril.

MR. C. TENNANT LEE, an analytical chemist, was present by invitation, and spoke as follows: The discussion of the subject of arsenical poisoning from wall-papers, which has been carried on here, is of a very in-

teresting character, and the cases are numerous and interesting, but the matter seems to rest on a very insufficient basis, and must certainly be considered as not proven. The cases so often classed by physicians as arsenical poisoning are most generally deduced from defective or careless observation, and are in reality not due to arsenic at all. I have been surprised to see how often I have been consulted in relation to the sanitary conditions of dwellings, in which some dreadful condition was supposed to exist, and have found a defective drain, a leaky closet, or some other hygienic fault, the remedial treatment of which has removed all symptoms of the threatened danger. It is often the case that a foul tank in connection with the furnace will cause serious and sometimes truly alarming symptoms, but these causes are seldom heard of by the physician or the public. The excitement at present in relation to arsenic is due in great part to the fact that the attention of the public is at present directed to this subject, and every one is thinking of it. When the scare about arsenic has abated, the number of cases supposed to be the result of poisoning from this source will become less, and substantially the same immunity from the trouble will be restored as existed before the people were so much aroused by this imaginary danger. Physicians make the mistake of frequently ascribing to arsenic those conditions which are due to quite another set of causes. The cases of arsenical poisoning thus far reported all end in recovery, and the entire history of the present craze is but two or three years old. It is far too early to be certain that these are cures, or that arsenic will produce such a varied series of clinical conditions. An example of the careless way in which physicians often account for strange symptoms by wrong theories was illustrated by a case in which a girl was sick in a room papered with an arsenical green paper. This was removed, but the girl died. Some sensitive persons are poisoned by simply passing by a bed of poison ivy. In a certain family a new carpet was bought, and from motives of economy, the family decided to sew the carpet themselves. Those engaged in this work soon fell ill, but on relaxing their occupation rapidly recovered. On resuming the carpet-sewing, the old symptoms quickly returned. The carpet was now examined by the physician and was found to be "full of arsenic." The carpet was then analyzed by a chemist, and not a trace of arsenic could be found in it.

Rose-aniline is made by reduction of the substance by means of arsenic. The scarlet shirts and stockings which cause so much irritation of the skin, do not, however, contain arsenic. They are colored by nitrobenzole colors, which are not arsenical. The workers in the manufacture of paris-green are said by their employers not to be injuriously affected by the nature of the substance on which they are employed. The skin of the employees is sometimes made raw, but they are not poisoned by the arsenic. There is one other point in which physicians are greatly in error. The opinion is generally disseminated throughout the profession that the arsenic is liberated as arsenuretted hydrogen. This is a great mistake, as arsenic cannot be liberated in any natural way in this form, and therefore cannot be a source of injury to the public in this form.

DR. CHARLES HARRINGTON asked Mr. Lee if he considered that a foul water-box in the furnace, or the

imagination of the patient, or the presence of sewer-air in the dwelling, can produce arsenic in the urine of the affected individual. Mr. Lee replied that he did not know, and asked in reply how it is that so many other causes are followed by symptoms identical with those of supposed arsenical poisoning?

Dr. Harrington said that much about the cases of poisoning by arsenic is not clear; but given a paper which is found to be arsenical, the patient presenting an array of symptoms which are recognized as accompanying arsenical poisoning, and arsenic being found at the same time in the urine of the patient, it seems fair to connect the symptoms with the arsenic.

PROF. HILL, of Cambridge, said that within the last few months he had seen but few cases of poisoning from arsenic, but formerly he had seen a great many of these cases with Dr. Sanger. The idea of establishing a *limit* to the degree to which arsenic may exist in wall-papers seems faulty, from the fact that there is no reason for the use of arsenic at all in the manufacture of wall-papers. There are occasionally substances used in the papers which may possibly contain a trace, but this is too insignificant to deserve notice. In most cases in which the paper is examined, the amount of arsenic is almost nothing or the amount is quite large. There is no medium grade. It is almost nothing, or the quantity is very great. Colors can now be easily obtained which are free from arsenic as an impurity, and those colors should certainly be employed in all papers.

PROF. E. S. WOOD, of Harvard University, was next called upon by the Chairman. He stated that much had been said about the way in which the arsenic is separated from the body of the paper. He thinks the chief danger to come from the dust which is constantly being given off from the paper, and which is contained in the air of the room, by which it easily comes in contact with the mucous membranes of the eyes, nose, and throat. It is needless to say that no color can be pronounced free from arsenic without a chemical analysis carried out in proper form. There is sometimes a discrepancy in the results obtained by different chemists, owing to the faulty tests often employed. No test can be considered as reliable, which does not insure the destruction of the organic matter in the paper tested, as the first step of the operation. There is no necessity that pigments containing arsenic should be used in the manufacture of wall-papers, and the American Wall-Paper Manufacturing Company now manufacture more papers which are free from arsenic than it did a year ago. This can always be secured by the preliminary analysis of the pigments employed. Even in painted walls arsenic may occur, and may produce the symptoms of poisoning. It seems useless to deny the danger of poisoning from arsenical wall-papers, when a person occupying a certain room is made sick; the person recovers on changing the room, and is at once again prostrated on returning to the former room; finally, on removing the paper from the room, or on removing to another house, the patient becomes free from all symptoms of trouble.

DR. R. STURGIS stated that a case of poisoning was known to him, in which the paper had been upon the walls of the room since the year 1873.

DR. HENRY CARMICHAEL, late of the Faculty of Bowdoin College, was introduced by the Chairman, and said that he had been occupied in the analysis of wall-papers during the last ten years, and that the co-

incident illness, the accompanying symptoms, were present at that time in the same form as they are observed to-day. Some of the papers analyzed in Maine contained no less than two and one-tenth grains of arsenic to the square yard. Since the State of Massachusetts has been agitating the passage of a law to limit the amount of arsenical contents in wall-papers, there has been a notable diminution of this substance in the papers analyzed in the State of Maine. There is no protection without analysis. No eye can discern where the arsenic is deposited, and no other means will adequately detect its presence. There is need of a clearer understanding upon another point. When we say that a paper is free from arsenic, what do we mean? If we mean that the paper does not present the indication of minute traces of arsenic, then it has not been my fortune to have discovered any papers free from arsenic. All papers will present the traces of small amounts of this substance, under any circumstances. Some of the ores used among the mineral pigments which are employed in the manufacture of wall-papers often contain arsenic as an impurity. Such is the ore of iron, which is extensively combined in the colors of wall-papers. In this combination the arsenic is absolutely inert, and is quite harmless. In fact this combination is almost identical with the preparation which is used in medicine as the antidote to arsenic in cases of acute poisoning. Another source of error is found in the fact that we are often inclined to lay the harm to the wall-paper when there are other substances from which the poisonous symptoms might occur with fully as much probability as from the paper on the walls, such as the colored fabrics of dress or the decorations or upholstery of the apartments.

DR. F. W. DRAPER spoke of his researches upon the dangers of arsenic to those employed in its use, or exposed to its influence. He said that he did not consult the employers of the men, or the contractors who did the work, but that he went directly to the men themselves. From them he learned that those men whose duty required them to be in the presence of the arsenic, and to handle it, were often sick, and not infrequently were obliged to suspend their labors. It is difficult to understand the statement made by one of the speakers at this meeting that constant employment in contact with so powerful and injurious a substance as arsenic should be without harmful influence upon those so exposed to it.

The Secretary read a communication from Mr. Gregory, a prominent dealer in wall-papers, regretting that illness prevented him from being present at the meeting.

PROF. WOOD suggested that all physicians who have cases of arsenical poisoning from wall-papers should send a sample of urine from the patient, together with a portion of the harmful paper, so that a quantitative analysis may be made, and at length a positive and accurate opinion be gained of the exact amount of arsenic which is capable of producing the symptoms of poisoning. Prof. Lyon said that he could place in the hands of the Society the proofs, in the form of letters, from thirty or forty families who have suffered from arsenical poisoning by means of wall-papers.

DR. G. E. FRANCIS, of Worcester, was then introduced by the Chairman, and after expressing his thanks for the opportunity of participating in the discussion,

said that he felt like offering a word of caution in relation to the accuracy of the opinion that all the disturbances so frequently ascribed to arsenic are in reality due to this cause. Before any further appeal is made to the Legislature we should be prepared to meet our opponents in every direction. Let us suppose that a paper which has been in service for twenty years has at length caused the appearances of arsenical poisoning. The analysis of the paper proves that it contains two grains of arsenic to the square yard. Now the question which must be answered is this: how much arsenic has been lost by the paper during the many years of service, if it still contains so large an amount at present. If the paper, after so long a time, still contains a large amount of the poison, then certainly it could not have lost much during that time; for the arsenic can be in only one place at a time. We should seek to ascertain how rapidly arsenic is dissipated by exposure to the air, and find out the rate at which it leaves the paper. We shall then certainly not be so liable to erroneous opinions and statements as we are at present.

DR. B. F. DAVENPORT stated that the papers of almost any manufacturers may contain arsenic even if the color is absolutely free from any appreciable amount of the poison. There are two principal questions: First, how much arsenic is really present in honest and well-selected papers? The second question is: What is the minimum quantity of arsenic which may induce the symptoms of poisoning? One undoubted form in which arsenic may be liberated is in the form of arsenuretted-hydrogen, from the presence of arsenious acid in contact with moulding substances, which evolve the hydrogen gas. In a case in which suicide was committed by the aid of "Rough on Rats," there was an evident odor of arsenuretted hydrogen on opening the stomach. The limit to which arsenic may be contained in wall-papers has received the attention of chemists all over the world, and only recently Prof. Pettenkofer has suggested that the safety of the public would not be imperilled if the amount of arsenic did not exceed fifty-five one-hundredths of a grain in each square yard.

DR. E. W. CUSHING asked Prof. Wood if there is any method by which a country physician may make an approximate analysis, or at least ascertain if there is any considerable amount of arsenic in a suspected paper?

PROF. WOOD said that the organic matter may be easily destroyed by the addition of a small amount of sulphuric acid, heating until the paper is thoroughly charred, and extracting the charred mass with water; the liquid can then be filtered and submitted to any of the common tests. If it is desirable to obtain the mirror of arsenic in a tube, it is advisable to employ a square decimeter of the suspected paper: if it is desired to produce the mirror upon a plate, a larger amount of the paper will be necessary, and the amount of arsenic required to form a mirror in this way will roughly be about one-tenth of a milligramme.

DR. CHADWICK, in closing the discussion said that he had but little to add to what had been said. He remarked that he would have replied to some of the observations of Mr. Lee, but as that gentleman had left the hall he would not revert to his remarks in his absence. It seems, however, a little like supererogation to be informed that a physician cannot discriminate between the symptoms of arsenical poisoning and

those occasioned by other diseases. Dr. Chadwick believes in continual agitation of this important matter, and hopes it will not be permitted to rest where it is at the present time. With an awakened public opinion, and a proper appreciation of the dangers attending the use of arsenical papers, it will not be difficult to frame a bill at the proper time, which shall cover the requirements of safety, and which the manufacturers will not oppose.

The Chairman then requested the Secretary to read the resolution offered by Dr. Chadwick, after which the question of adoption of the same was put. The vote was unanimous in favor of adoption of the resolution.

Adjourned at 10.20 o'clock.

#### MASSACHUSETTS MEDICAL SOCIETY.

##### COUNCILLORS' MEETING, WEDNESDAY, FEBRUARY 2.

A stated meeting of the Councillors was held at the Medical Library, Boston, on Wednesday, 2d inst.

The meeting was called to order at 11 A. M., by the President, DR. THOMAS H. GAGE. Sixty Councillors indicated their presence by signing the roll.

##### APPOINTMENT OF DELEGATES AND COMMITTEES.

On nomination by the Chair, the following delegates to other State Medical Societies were appointed:

*Maine:* Drs. R. T. Davis, of Fall River; J. A. Douglass, of Amesbury.

*New Hampshire:* Drs. J. M. Harlow, of Woburn; E. B. Harvey, of Westboro.

*Rhode Island:* Drs. J. H. Mackie, of New Bedford; Z. B. Adams, of Framingham.

*Connecticut:* Drs. J. P. Reynolds, of Boston; F. K. Paddock, of Pittsfield.

*New Jersey:* Drs. J. G. Park, of Worcester; J. Seaverns, of Roxbury.

Committees were appointed:

*To Audit the Treasurer's Accounts:* Drs. A. L. Mason, A. Wood.

*To Examine the By-Laws of District Societies:* Drs. S. D. Presbrey, J. C. White, F. W. Chapin.

The Committee on Membership and Finances reported names of Fellows to be allowed to resign, to retire, and also to be dropped for non-payment of dues, and their recommendations were adopted.

The President offered a very appropriate and feeling tribute to the memory of the late Dr. Joseph T. O. West, of Princeton, a Councillor at the time of his decease.

#### MEDICAL SOCIETY OF THE STATE OF NEW YORK.

EIGHTY-FIRST ANNUAL MEETING, HELD AT ALBANY, FEB. 1ST, 2D, AND 3D, 1887.

##### FIRST DAY.—MORNING SESSION.

THE Society was called to order at 10.20 by the President, DR. WILLIAM S. ELY, of Rochester.

##### THE PRESIDENT'S ADDRESS.

After thanking the Society for the honor conferred upon him in electing him to its highest office, and referring to the benefits to be reaped from attendance upon the meetings, Dr. Ely spoke of certain amend-

ments to the constitution and by-laws which he considered admirable. He recommended that hereafter the President be given discretionary power, when the amount of scientific material permits, to arrange for the formation of two or more sections for which he may appoint chairmen and secretaries. He also recommended that the committee on legislation be instructed to report at the next annual meeting as to the advisability of certain changes in the laws relating to the organization of the State and county medical societies and boards of health. He also recommended the addition of an "In memoriam" to the published transactions. The number of deaths among members, and particularly of eminent men, had been unusually great the past year.

The committee on the President's Address, appointed later, reported in favor of adopting all its recommendations excepting the one alluding to a change in the organization of the State and county medical societies. The committee's report was adopted.

DR. BENDELL rose to read the report of the committee on legislation, but DR. R. F. DRAKE objected, saying that Dr. Bendell had been appointed chairman of the committee by the President to fill the place of Dr. Roosa, who had been elected to the office by the Society but could not serve. The question was referred to the committee on by-laws, which reported later that the action of the President was not in accordance with the by-laws; but it recommended that his action should be supported in this instance, not intending, however, that it should be considered a precedent. The committee's recommendation was adopted, and after the report of the committee on legislation had been read, Dr. Roosa offered the following resolution, which was adopted,

*Resolved*, That, while the Medical Society of the State of New York approves of the report recommending the codifying of the present laws as regards medical matters, it does not relinquish the conviction, so often expressed, that it is necessary for the interests of the people and the profession that a law creating a Board of Medical Examiners be passed.

Dr. W. C. WEY related a case of

#### SUPPURATION AND DISPLACEMENT OF THE EPIPHYSEAL HEAD OF THE HUMERUS

in a child two weeks old. The rarity of the condition was remarked upon, as well as the fact that nature being allowed the opportunity effected a cure without aid.

#### ADAPTATION OF DR. CORNING'S METHOD OF PRODUCING LOCAL ANÆSTHESIA TO OPERATIONS ON THE EYELIDS.

DR. DAVID WEBSTER read this paper, in which he described the operation as adapted to the eye, in which class of cases, as well as in others, he had found it very useful. He employed cocaine-anæsthesia in nearly all operations on the eye, excepting enucleation.

DR. J. LEONARD CORNING followed with a paper entitled

#### MEDICATION OF THE NERVES OF THE SPINAL CORD.

The method of producing anæsthesia alone had been described when the allotted time had expired.

DR. PHELPS made some remarks upon the dangers of cocaine, and thought it should be given in no larger quantity than was really necessary.

DR. ROOSA had seen no ill-effects from cocaine, and thought it should be employed as frequently as desirable, but also in as small quantity as possible.

#### IS THE DANGER OF POST-PARTUM HÆMORRHAGE INCREASED BY THE USE OF ANÆSTHETICS DURING PARTURITION?<sup>1</sup>

DR. FORDYCE BARKER read the paper, and said that his experience with antiseptics in labor had been limited, since 1850, almost exclusively to chloroform, which he regarded as preferable to ether because the odor is less disagreeable; because it is less irritating to the respiratory tract; because it is more quickly effective and in less quantity. It should be used intermittently, only at the time indicated. Dr. Barker employed chloroform to relieve pain in most cases of normal labor, and said that heart disease was not a contra-indication to its use when any anæsthetic was called for. He believed that with proper care no woman should die of post-partum hemorrhage due solely to uterine inertia. Chloroform hastened much oftener than it retarded labor. It could not be shown to exert any injurious influence on mother or child. The only case on record of death after chloroform in labor, in care of a competent practitioner, was one in which the anæsthetic had been preceded by convulsions and it was not proven that chloroform was the cause of death. Dr. Barker said he had never had post-partum hemorrhage occur in any of his cases except one, and in that chloroform had not been used.

DR. E. L. PARTRIDGE said that an important advantage in the use of an anæsthetic was the fact that the physician was better able to perform his manipulations, and was less likely to injure the patient in any way, when he knew that she was experiencing no pain. Another reason why an anæsthetic should be used was the fact that when the woman was allowed to suffer unduly, her nervous system seemed to become affected for sometime afterward, this being manifested in the presence of various nervous symptoms. He admired the terse statement of the author that uterine exhaustion was frequently called uterine inertia. A disadvantage in the use of ether was that usually it was called for at night, in a small room, and there was danger of explosion. Notwithstanding the fact that he very commonly employed chloroform, yet he had some fears.

DRS. SHERMAN, HEWLETT and CASTLE employed chloroform in labor.

DR. HEWLETT had had one case of post-partum hemorrhage due in part, he thought, to the use of chloroform.

DR. McLAURY had recently given up chloroform for hydrate of chloral.

DR. S. B. WARD still had fears of chloroform, even in labor, and employed ether, the effect of which, he said, was much quicker than many supposed, as a few whiffs from a towel would put the patient beyond pain.

DR. BARKER said his friend Playfair also employed hydrate of chloral, but an *à priori* objection was that its action must be continuous.

#### CORRECTION OF THE DEFORMITY OF PUG NOSE BY A SIMPLE OPERATION.

DR. JOHN O. ROE said the size of the pug nose would appear to be increased if the end or a portion

<sup>1</sup> See page 125.

causing the pug was removed, leaving the outline regular. The operation which he performed consisted in lifting the end of the nose and dissecting from beneath a sufficient amount to correct the deformity on returning the integument to its place. Too much should not be removed, and the integument should not be cut through, lest a scar be left. Malformation due to deformity of the cartilage could be corrected by incisions through the cartilage and use of internal and external splints. Five patients operated upon in this manner had had their physiognomies greatly improved.

Question of admission of delegates from medical associations of northern New York was raised, and later the Committee on By-laws reported that while in favor of admission of the gentlemen, as delegates, yet the committee could not report before the next annual session whether such action would be lawful. Report of the committee was adopted.

#### CONCERNING THE INFLUENCE OF SMALL QUANTITIES OF SODIUM, CALCIUM, AND POTASSIUM SALTS UPON THE CARDIAC AND SKELETAL MUSCLES OF THE TORTOISE.

SIDNEY RINGER, of London, sent the paper which was read by Dr. Stoddard. The conclusions from the experiments were, that saline solutions, when circulating through the system in such a way as to come in contact rapidly with muscular protoplasm, induce lessening or loss of contractility, and do so with great rapidity. Their action is exerted alike on cardiac and skeletal muscles. Lime and potassium salts brought into like intimate relation to muscle-protoplasm possess the power of exciting muscular contractility. Lime salt speedily restored contraction when stopped by saline solutions. These facts hold good for the heart muscle of the eel, the frog, and tortoise, and skeletal muscles of tortoise as well.

#### RESULTS OF MULTIPLE PARACENTESIS OF DRUM MEMBRANE ON THE HEARING IN CHRONIC AURAL CATARRH.

DR. O. D. POMEROY, in performing this operation, guarded against undue injury of the membrane. The operation was usually attended with little pain. Cocaine might be employed. In not a single instance had a considerable amount of inflammation of the membrane resulted, and the hearing in none had been lowered. On careful examination he was compelled to admit that the patient's statement was true regarding much improvement in hearing. Some of the cases had been under observation two years, and no tendency to relapse had been noticed. Twenty-four cases were reported.

#### IS MODERN MIDWIFERY MIDDLE-AGE?

DR. DAVID LITTLE showed conflicting views regarding utility of supporting perineum, of Credé's method, of immediate operation for lacerations, of use of antiseptic injections, etc. His restrictions applied only to cases of normal labor. When all goes well in this physiological process, he said, let well enough alone.

DR. FORDYCE BARKER agreed with the author in most of his statements. He, however, practiced Credé's method. He objected to the fashion of attributing all cases of rise of temperature after delivery to septic poisoning, and gave instances in which anti-malarial treatment had caused its return to normal.

DR. LAWRENCE JOHNSON opposed the use of anesthetics in normal labor, and their use was often rendered unnecessary in other cases by use of forceps, to the better welfare of the patient.

DR. J. S. WHITE then read a paper entitled

#### A CASE OF DISLOCATION OF HEAD OF LEFT FEMUR UNDER PUBIC ARCH.

It was followed by a paper from DR. EMMET HOLT,

#### A PLEA FOR MORE CAREFUL INVESTIGATION OF URINE IN YOUNG CHILDREN.

Up to the present time little attention had been given to nephritis in infants, except as a complication of infectious diseases. For this reason the urine in other diseases of infants was seldom examined, and it was probable many cases of nephritis were thus overlooked. Within the last few months the author had seen six cases, and a friend had reported two more, making eight cases of renal disease in infants under two years, not complicating any infectious disease. The symptoms were described. Five of the cases proved fatal. Different means for collecting urine were mentioned. The best was the use of the catheter, a napkin, or a condom might be employed.

#### SOME IMPORTANT POINTS IN THE MANAGEMENT OF DEEP URETHRAL STRICTURE.

was the title of a paper read by DR. F. N. OTIS. Out of a large number of cases of urethral stricture which had come under his observation, less than ten per cent. were situated beyond a point four inches from the meatus. The large majority of strictures were in the penile portion.

In dilating the stricture the sound should not be introduced through the deeper portion when healthy.

#### FIRST DAY. — EVENING SESSION.

#### CONCERNING STATE AND PREVENTIVE MEDICINE

was a paper read by DR. MERCER, of Syracuse, only an abstract of which was read. It contained an outline of sanitation from ancient to modern times. He suggested the founding of a sanitary organization, which should be composed of all interested in such matters throughout the State.

DR. DAVID LITTLE exhibited a modified Barnes's dilator for use as a "dinner-pad" in the application of the plaster-of-Paris jacket.

#### ON THE INTOXICANT HABIT.

DR. H. R. HOPKINS, of Buffalo, in considering this subject, referred not alone to the use of alcohol, but also of cocaine, morphine, etc. He believed the medical profession was in a great degree responsible for the increase and existence of the intoxicant habit in all its varieties, but the alcoholic least.

DR. WEY, of Elmira, discussed the paper, confining his remarks to the alcoholic habit, which, he thought, was best treated in inebriate asylums, where the patient's appetite could be restrained. The State, he thought, could not rightly limit the sale of alcohol through a high license, as it was taking from citizens the equal right to engage in business.

#### REMARKS ON INTRA-UTERINE MEDICATION

were made by DR. T. A. EMMET, who, inasmuch as he was opposed to such medication, went back some years, tracing the development of his present convictions on the subject. He even opposed the use of hot

water. In reply to some remarks by Dr. Gill Wylie, he said that if there was a definite pathological lesion in the uterus, as the presence of a polypus, he would treat it. He no more introduced the uterine sound, or made applications to the endometrium. His patients left his hospital cured in a much shorter time now than formerly, when he employed intra-uterine medication. His views upon cellulitis were incidentally referred to.

#### ON THE NECESSITY FOR COMPLETE REMOVAL OF THE UTERINE APPENDAGES WHENEVER OPERATION IS CALLED FOR.

DR. ALBERT VAN DER VEER, of Albany, related six cases, and in his remarks said that he was deeply impressed that many so-called nervous cases subjected to this operation, are cases which ought to be relieved by some medication, and he desired to state that in the cases reported such treatment had been faithfully tried without avail. Several of the patients were not permanently cured after removal of the uterine appendages.

A paper on this subject was sent by MR. LAWSON TAIT, read by DR. S. B. WARD, entitled

#### THE RESULTS OF UNILATERAL REMOVAL OF THE UTERINE APPENDAGES.

MR. TAIT asked the question, would it not be better to advise complete removal of the uterine appendages in any case where the operation is demanded by the presence of disease, even if limited to one side?

This was his first contribution toward the solution of this question, and it contained an analysis of his first thousand cases of laparotomy, prior to 1884, twenty-six of which had a bearing on the question. One of these was useless, as the patient had died. In conclusion, he said that though the number of cases was small, he was yet becoming more convinced that, when the patient's sufferings were sufficient to justify laparotomy, it was better to remove the entire uterine appendages, although there was disease upon but one side. He preferred the term, "uterine appendages." It was absurd to name an operation after an operator.

DR. T. A. EMMET said that Battey's operation, in his opinion, should rarely be performed. He thought removal of the uterine appendages was done far too frequently in this country. He seldom saw a case in which the operation was indicated, yet he saw many cases called by some authors salpingitis, and he cured them too.

DR. GILL WYLIE had removed the appendages on one side only in four cases, at least. Two had since borne children. In one, neuralgia developed in the other ovary, which was then removed, and the patient is now well.

#### SECOND DAY.—MORNING SESSION.

DR. PARKER offered the following preamble and resolution, which were adopted:

*Whereas*, It is in the knowledge of this Society that in one or more counties of this State a vote has been carried by a majority to disband or dissolve the County Medical Society; and *whereas*, the minority in such societies are not informed as to their rights and duties in such circumstances, therefore, it is hereby resolved, that the Committee on Legislation is instructed to consider the matter, and formulate such directions as may be wise for the instruction of those desiring to

rehabilitate such societies, and to obtain possession of the records, moneys, libraries, or other property in possession of the old society at the time of its dissolution, such committee to report at the next meeting of this Society.

#### REPORT OF THE COMMITTEE ON HYGIENE.

DR. STODDARD read the report, which showed an improvement in the sanitary condition of public institutions throughout the State generally, but it was evident there still remained much work to be done by the members of the Society individually. The facilities for bathing had been much improved. In connection with this report, a bill before the Legislature, providing for the establishment of a hospital for contagious and infectious diseases, pertaining to King's County, was read.

DR. A. G. GERSTER then read a paper on

#### ANTISEPTICS IN PRIVATE PRACTICE AND EMERGENCIES.

and presented a bag for antiseptic surgery, containing the following:

One bottle, two ounces, in wood box, with corrosive sublimate; box marked, "Corrosive sublimate, 1; alcohol, 10; one teaspoonful to a quart of water; strength, 1 to 1500." One bottle, four ounces, in wood box, carbolic acid, pure; marked, "Four teaspoonfuls to a quart of hot water; shake well; strength, three per cent." One bottle, two ounces, in corrugated tin box, chloroform. One bottle, four ounces, for catgut ligature, in corrugated tin box, with glass reels. One dusting box, hard rubber (Gerster's), for iodoform. One tin can, with one-half pound of ether. One long glass jar, with rubber cork and metal screw top, for rubber drainage tubing, with five parts carbolic solution to one hundred parts water. One long glass jar, like above, for compressed carbonized sponges. One large broad-handle scissors, stout, for cutting gauze. One stout ring-handle dressing forceps, for drawing forward tongue in anaesthesia. One razor, one teaspoon, one piece of wax. One Ormsby's Ether Inhaler, and one Esmarch's Chloroform Mask, both enclosed in rubber-cloth bag. One large-size fountain syringe, with three glass points and rubber tubing; also in rubber-cloth bag. One hypodermic syringe, in metal case, with screw cap to prevent evaporation, for probatory puncture. One stiff nail-brush, solid wood back. One dozen large and small safety-pins. One white linen pouch, for the reception of instruments. One nest, six tin cups, block-tin, six inches in diameter. One nest, six large, square tin basins. The valise has loops inside for holding the bottles and the various articles; an inside pocket for small articles, and an outside pocket for dressings. The valise is placed in the nest of tin basins, and is fastened to the same by two leather straps. Size of valise, eighteen inches long by eight and one-half inches wide.

#### ON THE MANAGEMENT OF SOME FORMS OF VARICOEQUUS.

DR. PHELPS demonstrated his manner of treating certain cases of varicoequus. He first divided the contracted soft parts, and if this did not overcome the deformity, the bones being at fault, he cut this, and, if necessary, took out a V-shaped piece. Further resistance was overcome by an apparatus into which he placed the foot after applying a water-glass and a plaster-of-Paris dressing. The foot having been forcibly brought into a correct position while the patient was under the anæsthetic, it was left in the apparatus until the dressings hardened.

DR. LUCIEN HOWE, of Buffalo, read a paper on

#### THE COMPARATIVE VALUE OF ANTISEPTICS.

He first defined the terms antiseptic, disinfectant, and germicide. He showed the unreliability of the clinical test as to antiseptics, etc., and showed that the safest test was by using the agents for destroying the germs after having obtained pure culture specimens. The object of the paper was to demonstrate

the fact that these experiments or tests could be carried out with comparative ease and without a great deal of expense. A simple method for photographing microscopical specimens was exhibited, the object sought was to show what solution in what strength would stop the growth of the germs.

#### THE TREATMENT OF REDUCIBLE AND IRREDUCIBLE HERNIA, BY HEATON'S METHOD.

DR. R. F. WEIR first described Heaton's method of operating, and then spoke of certain details of the operation which he had altered, he thought, for the better. First, he used a somewhat longer and thicker needle; he introduced by a boring motion; when it entered the canal it was indicated by a sensation as if a slight obstacle, as a piece of writing paper, had been passed. He and his colleague, Dr. Abbe, had operated upon about seventy cases, the percentage of cures being a little over twenty-nine. Dr. De Garmo, he said, had reported a number of cases, claiming as the percentage of cures about forty-five. For cases in which Heaton's method was not practicable, he resorted to the radical operation, which he also described, and said that the relapses under this mode of treatment, as shown by statistics, was thirty-nine per cent., while the mortality had been a little less than three per cent.

DR. ROSWELL PARK, of Buffalo, had performed only Czerny's operation, and he had been very well satisfied with it. He had operated in between twenty and thirty cases, and none had returned with a relapse. He fixed a portion of the omentum in the wound, and thought it went to prevent a relapse.

DR. GILL WYLIE spoke of the prevention of hernia after laparotomy, the important point being to bring like tissues in contact when closing the abdominal wound.

DR. DE GARMO and DR. WEIR spoke emphatically against leaving a part of the omentum in the wound in the radical method.

#### TOBACCO AMBLYOPIA.

DR. HERMAN BENDELL, of Albany, read a paper on this subject, in which he took the ground that analogy would indicate the possibility of tobacco amblyopia, and his clinical observation went to support this view. Time did not permit of his reciting cases. He thought it occurred most commonly in those who used strong tobacco. The prognosis was not favorable, but in any case he thought the patient should absolutely abstain from the use of tobacco.

DR. ROOSA said that out of a large number of patients seen at institutions, he had not been able to trace one case of amblyopia directly to the use of tobacco. Facts were wanted in discussing this subject, and not theory.

#### PAROXYSMAL CARDIAC DYSPNOEA.

DR. A. L. LOOMIS read the paper. In very many valvular diseases of the heart, when accompanied by hypertrophy and secondary dilation, dyspnoea was a prominent symptom, but the dyspnoea was of gradual development. In the paroxysmal cardiac dyspnoea to which he referred, the symptom was due entirely to the state of the heart and the consequent arrest of pulmonary circulation, more or less complete, and not to any organic lesion in the lungs obstructing the entrance of the air to the air cells. Under whatever

diseased condition this form of dyspnoea arose, it had this one essential cause, namely, temporary or permanent arrest of blood in the heart or pulmonary arteries, and consequently it must either be paroxysmal, or suddenly terminate in death. The cause of the symptom was, in most cases, a thinning and consequent weakening of the cardiac muscle. There might be other lesions, but the frequent absence of signs of valvular lesions was what led to the patient's danger. He had found defibrinated blood entwined about the valves and in the heart cavities. If the right side of the heart was principally affected, the blood-supply would be shut off from the lungs, leaving them bloodless, and the other internal organs engorged. If the obstruction existed in the left side of the heart, the blood-current would be arrested in its passage to the aorta, the lungs would be found intensely congested, while the other internal organs had less than their normal amount of blood. The time when the paroxysm was most likely to come was in the early morning. When it came on, the patient constantly changed his position, hoping for relief. The pulse is feeble, irregular, intermittent. Frequently there is prolonged absence of the radial pulse. The return of the pulse precedes instead of follows the subsidence of the dyspnoea. The mind remains clear. If death took place, the final act was one of persistent muscular contraction. The treatment to be encouraged should be instituted in patients threatened with paroxysmal cardiac dyspnoea, instead of after the attacks had begun.

#### THE CLINICAL SIGNIFICANCE OF ENDOCARDIAL MURMURS.

DR. W. M. CARPENTER read the paper, the object of which was to further impress upon the minds of the medical profession certain facts well known to some, stated as follows: First, that endocardial murmurs and chronic valvular disease of the heart are not synonymous terms. Second, that the existence of a persistent endocardial murmur is not inconsistent with long life and the enjoyment of a fair degree of health. Third, that the knowledge, on the part of the patient, of the presence of an endocardial murmur, should guard him against exposure to all influences that may give rise to any of the diseases which are liable to have cardiac disease as the sequel, or that will cause increased cardiac action.

#### DEMONSTRATION BY DR. O'DWYER, OF NEW YORK, OF HIS METHOD OF INTUBATION OF THE LARYNX.

DR. O'DWYER traced the gradual improvement of the instrument used in this operation since he first began his experiments on the cadaver, about six years ago. Within a year he had practiced intubation of the larynx in about fifty-seven cases, refusing to do the operation on none, it mattered not how near death's door they had come. Out of this number fourteen lives had been saved.

(To be continued.)

— At a recent meeting of the Paris Société Thérapeutique, M. Blachez reported the administration of gaseous injections of sulphuretted hydrogen in three cases of chronic pulmonary disease, in two of which positive benefit was experienced. In the third case there was no satisfactory improvement of the lung symptoms, and some gastro-intestinal irritation was induced.

## Recent Literature.

*The National Dispensatory, containing the Natural History, Chemistry, Pharmacology, Actions and Uses of Medicine, including those recognized in the Pharmacopæias of the United States, Great Britain and Germany, with Numerous References to the French Codex.* By ALFRED STILLE, M.D., and JOHN M. MAISCH, Phar. D. Fourth Edition. Revised and Improved. Philadelphia: Henry C. Lea's Son & Co. 1886. xvi. 1781.

This, the most comprehensive of the several commentaries upon the Pharmacopæia of the United States, Great Britain and Germany, which has yet appeared, has by this last revision been brought fully up to the existing knowledge upon the subject treated. Its references to the British Pharmacopæia have been amended for the late and much-changed new edition of that work; an "addenda" of twenty-five pages has been appended, treating of some twenty-four of the latest and more important additions to the materia medica, among the most noteworthy of which are Antipyrine, Cocaine Hydrochlorate, Iodol, Lanolin, Thalline, and Urethane. This work should be in the hands of every physician and pharmacist.

*Handbook of Practical Medicine.* Vol. III. By DR. HERMANN EICHHORST. 157 wood engravings. 8vo. pp. viii. 390. New York: Wm. Wood & Co. 1886.

This third volume of the translation of Eichhorst's great work, the October number of Wood's Library, contains the sections on the diseases of the nerves, muscles and skin. The first striking feature is that nowhere, either in this volume or the others, does the author discuss the diseases of the oculo-motor nerves and their nuclei. With this exception, however, the author gives a reasonably full account of the diseases of the nervous system. This portion of the work, however, seems to us hardly equal to the other volumes. In aetiology and minute pathology it is superior to any work of the size with which we are familiar, but its description of the symptomatology of disease, although full of valuable points, lacks that systematic arrangement and clearness which might make it suitable for the student. Portions of it, too, notably the chapters on neuritis, alcoholic paralysis, and Thomsen's disease, have been rendered of less value by the great additions to our knowledge made since their original publication. The chapters on the skin contain a good though a brief account of its diseases. Although not the best manual for the student, this volume is of great value as a work of reference, and we are glad that it is now accessible to the English reader. We cannot speak highly, however, of the work of the translator. The style is harsh and follows the German idiom too closely, and in the paragraphs on treatment the parentheses and abbreviations cause needless obscurity. On page 13 the misplacement of the word "only" causes the author to make the astounding statement that the third branch of the fifth "contains only motor-fibres," which is a fact known only to the translator. The mechanical execution of the book is cheap, and the illustrations, except in the chapters on skin diseases, are wretched in execution, and many of them are so obscure as to aid but little in explaining the text.

*Paralyses, Cerebral, Bulbar, and Spinal: A Manual of Diagnosis.* By H. CHARLTON BASTIAN, M.A., M.D., F.R.S. 8vo. pp. xi, 671. New York: D. Appleton & Co. 1886.

This work is more than a manual of diagnosis of paralysis; it might well be called a manual of topical diagnosis of diseases of the central nervous system, and, although not always in accord with our present views, it is a clear and admirable work, and will be of much value to every one who wishes to be able to localize the lesion in cases of structural nervous disease.

The first half of the book is devoted to paralyses of encephalic origin, and takes up, first the pathological conditions that may cause paralysis, and the clinical indications of these several conditions. Then it considers the individual symptoms with regard to their significance in topical diagnosis, and finally the indications of disease in the various regions of the brain. The arrangement is comprehensive and satisfactory, the descriptions are clearly written, and the occasional tables for diagnosis are admirable. The author maintains his former view that the centres in the central convolutions are really "sensory centres of a kinesthetic type," "cerebral termini for impressions from muscles," more or less closely interlaced. The author is disposed to agree with Charcot's old theory that it is doubtful whether a cortical lesion can cause hemianopsia, and he still clings to the hypotheses of a centre for monocular vision in the angular gyrus and of a double decussation of the optic tracts; hypotheses which Seguin's recent work has disproved. He omits any mention of paralytic attacks in general paralysis and of paresis of the trunk muscles in hemiplegia, and the section on secondary degeneration neglects the recent work of Pitres, Sherrington and others.

Paralyses from diseases of the medulla are treated very satisfactorily on the same plan, and then a chapter is given to the motor and sensory paralyses of the cranial nerves, which is a fairly full and accurate account of the symptoms. It would have been better if some account had been given of the changes in the field of vision in the early stages of optic atrophy, which is at times of great value in diagnosis.

The final part, on paralyses of spinal origin, seems to us hardly equal to the rest. Adamkiewicz's investigations have been overlooked in dealing with the vascular supply of the spinal cord, and the discussion of the reflexes is rather unsatisfactory. The author maintains that a non-inflammatory softening of the cord is the ordinary lesion in "acute myelitis," and that a true inflammation is rare. He classes alcoholic paralysis among the functional diseases of the cord, where we also find "paraplegia from idea" and hysterical paraplegia, — a rather peculiar classification in the light of our present knowledge. He also makes the remarkable statement that in hysterical paraplegia he has seen absence of the patellar reflex. His whole classification of spinal diseases is rather vague, for he arranges them according to the acuteness of their onset, and his classes necessarily overlap. The book contains one hundred and thirty-six illustrations, most of which are old friends, but we are sorry to add that the reproduction of the illustrations is poor.

— The mortality in labor in China is said by a contemporary to amount to eight per cent., or about four hundred thousand deaths annually.

THE BOSTON  
Medical and Surgical Journal.

THURSDAY, FEBRUARY 10, 1887.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 283 Washington Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES, UPHAM & COMPANY,  
283 WASHINGTON STREET, BOSTON, MASS.

ARSENICAL WALL-PAPERS.

PUBLIC attention has again been called to the subject of arsenical wall-papers by a paper read by Dr. J. R. Chadwick at the meeting of the Section for Clinical Medicine, Pathology and Hygiene of the Suffolk District Medical Society, January 12, 1887. The discussion which followed the reading of the paper was broad in its scope and interesting in its character. Dr. Chadwick demonstrated conclusively the unreliability of many of the guarantees which have been hitherto presented by the paper-dealers regarding the freedom of their papers from arsenic, and thus emphasized forcibly the necessity of a uniform method of analysis, and such a method as will detect with certainty at least the minimum amount of arsenic likely to be injurious. We have good authority for the statement that papers containing the equivalent of two grains of arsenious oxide to the square yard have been pronounced by chemists, in Boston, free from arsenic, presumably as a result of objectionable methods of analysis. Whatever differences of opinion may exist regarding the final test employed, we fail to see how any exception can be taken to the statement made by Prof. E. S. Wood, in the course of the discussion, that no test can be considered reliable which does not secure the destruction of the organic matter of the paper as the first step in the operation; yet this step as a preliminary to Marsh's test is, we have reason to believe, frequently omitted in the analysis of wall-paper.

The clinical aspects of the subject were well illustrated by a series of cases in which recognized symptoms of arsenical poisoning were finally traced beyond reasonable doubt to wall-paper. The fact of arsenical poisoning from wall-papers is so well established, that we do not consider it necessary at this time to place before our readers the evidence which can be adduced to substantiate it.

We have, however, a word or two of comment to make upon the remarks of a chemist, Mr. C. Tennant Lee, who claimed that poisoning from arsenical papers rests on a very insufficient basis and must be considered

as not proven. Mr. Lee's remarks were characterized by a surprising degree of ignorance, not only of the matter under discussion, but of matters purely chemical. He argued that most of the cases which have been attributed to arsenical poisoning are in reality due to defective plumbing, or to some other fault in the sanitary condition of dwellings — more particularly, however, to foul water-boxes in furnaces — and he very impudently intimated that the physician cannot discriminate between symptoms of arsenical poisoning and those caused by other diseases.

The whole question of poisoning from arsenical papers is apparently new to Mr. Lee; so we judge from his remark that its entire history is but two or three years old. We do not propose to argue the matter with Mr. Lee. We believe it would be useless. It may not be amiss, however, to call his attention to the fact that, in a majority of the most authentic cases, the possibility of arsenical poisoning has been the last one thought of, and the paper has been submitted for analysis only after every other cause for the symptoms has been eliminated. Mr. Lee's ignorance on matters purely chemical is well illustrated by his remarks on the nature of the process which takes place in the manufacture of rosaniline, and by his statement that arsenic cannot be liberated in any natural way in the form of arseniuretted hydrogen.

Dr. J. M. Harlow made a brief statement of some of the reasons, as they appeared to him, for the failure of the bill presented to the last Massachusetts Legislature to become a law. Dr. Harlow was chairman of the Committee on Public Health of that Legislature, and his opinions on the legislative side of the question are entitled to careful consideration. While agreeing with him that any law which is asked for should include certain other domestic articles which frequently contain arsenic — such as children's toys, kindergarten papers, etc., and fabrics colored with Paris green — we do not believe it is advisable to include fabrics as a class. For, in the case of many fabrics we are not able to establish that close relation between cause and effect which we often are with wall-papers, and which the speaker rightly characterized as the greatest element of success in an undertaking of this kind. Fabrics contain other substances besides arsenic, which, there is reason to believe, may be a source of injury; for example, compounds of chromium and antimony, which are used as mordants. We are not as yet in a position to say that many of the colors themselves are not injurious, especially when they are brought into contact with the skin. We cannot, therefore, in the present state of our knowledge, say, when we find arsenic in a fabric which has caused poisoning, that the arsenic and the symptoms observed certainly stand in the relation to each other of cause and effect, unless arsenic should be detected in the urine. The introduction of fabrics, as a class, into any bill would, we believe, arouse additional opposition sufficient to endanger its passage.

Dr. Harlow believes that a law should establish a

limit to which arsenic may exist in wall-papers without being considered dangerous to health. Prof. H. B. Hill, on the contrary, believed a limit unwise, because there is no reason for the use of arsenic at all in the manufacture of wall-papers. We think Dr. Harlow takes the right view of this matter. By reason of its wide distribution minute traces of arsenic are very common, and we believe it is the uniform experience of chemists who employ the Berzelius-Marsh test in the analysis of wall-papers, that a large proportion of such papers contain traces of arsenic which may be regarded as unavoidable or of no account whatever. If chemists will agree upon some amount of arsenic which can fairly be considered unavoidable, and will further agree to report all papers containing less than that amount "free from arsenic"—meaning thereby free for all practical purposes—there may be a justification for the position taken by Prof. Hill. So long, however, as chemists employ the Berzelius-Marsh test, and report as arsenical, papers containing one, two, or three milligrammes of arsenic to the square meter, a limit is necessary.

There is, however, another reason why a limit is desirable. The manufacturers and dealers appear to be better disposed now than they were a few years ago, when it was impossible to convince them that papers contain any arsenic at all. The paper-dealers were represented in this discussion by Mr. N. W. Bumstead, of the firm of J. F. Bumstead & Co. The dealers do not believe in the possibility of poisoning by wall-papers. But they do acknowledge at the present time that a certain number of papers contain arsenic; though they claim to use every effort to obtain papers free from arsenic. The most prominent dealers in Boston have for a number of years secured analyses of their papers, and at the present time they have an agreement with the manufacturers whereby all papers containing more than a trace of arsenic are returned. The result is well shown in some figures given by Dr. Hills, from which it appears that, while a few years ago over thirty per cent. of all the papers examined by him were strongly arsenical, at the present time only thirteen per cent. contain anything over a trace of arsenic; and in most of these the quantity is comparatively small. The experience of other chemists who have occasion to examine large numbers of papers, is, we believe, similar.

As the matter now stands, we are not sure that it is impossible to fix a limit which shall satisfy the requirements of safety and which will be acceptable to the manufacturers and dealers. If so, the chief opposition to legislation will disappear. We believe that the opposition of the dealers at the present time arises, almost entirely, from a fear that they will not be fairly treated by the chemists, and we feel that the question of limit is to be an important one in future attempts to obtain legislation. What that limit should be, we are not now prepared to suggest. We would not place it as high as is suggested by Petenkoff (fifty-five one-hundredths of a grain per square yard),

but it is well to consider, before going to the legislature again, whether the limit asked for a year ago was not somewhat too low for practical purposes.

The undue importance attached to the arseniuretted theory may also be mentioned as one of the factors which, in our opinion, contributed to the defeat of legislation last winter. There is no doubt that this gas, or some other volatile compound of arsenic, may be evolved when compounds of arsenic are left in contact with fermenting and decomposing organic matters. There are reasons for believing too that this fact explains in certain cases the evil effects resulting from arsenical wall-paper; but after a careful consideration of the experimental evidence, we are forced to acknowledge that our information on this point is far from satisfactory. It is a subject calling for careful investigation. At the same time we should not lose sight of the fact, that most of the cases of poisoning from arsenical papers are undoubtedly due to the introduction of the arsenic into the system in the form of dust; and in future attempts at legislation we should carefully refrain from attaching any more importance to the arseniuretted hydrogen theory than the facts known will warrant.

Prof. E. S. Wood suggested that all physicians who have cases of arsenical poisoning from wall-paper should send a sample of the patient's urine, together with a piece of the paper, so that a quantitative analysis may be made, and at length a positive and accurate opinion be gained of the exact amount of arsenic which is capable of producing symptoms. A general compliance with this suggestion can hardly fail to furnish useful information.

Dr. G. E. Francis thought we should seek to ascertain if paper loses any arsenic while on the wall, and if so, the rate at which the arsenic leaves the paper. Dr. Francis's idea, if we understand him correctly, is to estimate the amount of arsenic in the paper after it has been on the wall a certain number of years, and compare this amount with that contained in the paper which has never been upon the wall. We do not believe any trustworthy information can be gained by this method of investigation. Given a loss in the amount of arsenic after a certain number of years, we can never be certain that a portion or all of such loss has not been caused by the friction to which the paper has been subjected in applying it to the wall or in removing it. That arsenic is lost in many cases has already been satisfactorily demonstrated by its detection in the dust of the room.

Dr. W. B. Hills expressed a belief that the matter might settle itself in a year or two, basing this belief on the fact that the proportion of arsenical papers had already diminished very materially, owing to the efforts of the manufacturers and dealers to meet the demands of the public. We should not, however, lose sight of the fact that any immunity we may possess at the present time, or hereafter, has been obtained only under the pressure of public opinion, and that, if this is removed, we may in a few years become again ex-

posed to as great dangers as we have been heretofore. Whether, therefore, a law is to be again demanded or not, the matter should not be allowed to rest where it is at the present time. It should, we think, be referred to a committee of physicians and chemists for careful consideration. Should it be decided to go before the legislature again, such a committee could, in our opinion, present the evidence much more satisfactorily than it was presented a year ago.

#### REDUCING SUBSTANCES IN THE URINE.

BOEDECKER, in 1861, was the first to call attention to the possible presence in the urine of a peculiar reducing substance, called by him alkapton, which reacts chemically in some respects like grape sugar, and which may therefore in rare instances be mistaken for the latter. In 1875, Fürbringer reported a second case in which the urine contained the same or a similar body.

Urine containing the so-called alkapton reduces strongly the salts of copper, and upon addition of potassic hydrate (Moore's or Heller's test) becomes dark from above downward, owing to the absorption of a large amount of oxygen. It does not (in the absence of sugar) reduce the subnitrate of bismuth, neither does it respond to the fermentation test. With indigo-carmin the same play of colors is produced as with urine containing sugar, but upon afterwards shaking with air, the reverse change does not take place, as is the case with urine containing sugar.

Similar cases have been observed by Ebstein and Müller, Dr. Armstrong, of Dublin, and still more recently by Dr. Robert Kirk and Dr. Frank Donaldson. Ebstein and Müller concluded, from their investigations, that the so-called alkapton is identical with brenzcatechin (pyrocatechin, oxyphenic acid) which, according to Baumann, is a very frequent, though not constant ingredient of human urine, and is always present in the urine of horses, occurring partly in the free state, partly in combination with sulphuric acid. The urine in Dr. Armstrong's case was examined by Dr. W. G. Smith, whose investigations led him to believe that the substance in question was protocathechuic acid; while Dr. Kirk, after a careful comparison of the reactions of the urine reported by him and of the peculiar body isolated from it, with those of pyrocatechin and protocathechuic acid, concluded that in his case the substance was different from either of these, and he proposed for it the name *urhodonic acid*.

The case reported by Dr. Donaldson is of peculiar interest, from the fact that the person by whom the urine was passed had been repeatedly rejected by life insurance companies because of the presence of sugar in his urine. There was, however, no clinical evidence of diabetes; the patient was in apparently perfect health, and in the past three years had gained in weight and girth. The specific gravity of the urine was normal. Dr. Tyson was finally called in consul-

tation, and, upon examination of the urine, concluded that the reducing substance was not sugar, an opinion in which Professor Wormley coincided. Dr. T. Barton Brune<sup>1</sup> and Dr. John Marshall have, entirely independently of each other, made a careful study of the urine in this case, and have described in detail the reactions of the urine and of the reducing substance isolated from it. Dr. Marshall believes the substance to be a hitherto unrecognized acid, and he proposes for it provisionally the name *glycosuric acid*. Dr. Brune says that it is not protocathechuic acid, although closely resembling it, and that it is apparently identical with Kirk's "*urhodonic acid*."

While we are not at present able to say positively that the peculiar reducing substances in the cases thus far observed are identical, we are inclined to believe that such is the case. It has not yet been shown that this substance, whatever it may be, has any pathological significance. It is perhaps worth mentioning that a majority of the cases have been in children. In one case only, we believe, was sugar present. It is, therefore, very important to bear in mind the fact, not generally understood apparently, that the reduction of the alkaline copper solution should not be relied upon as evidence of the presence of sugar, especially in cases where the clinical evidence does not point to diabetes mellitus, but should be supplemented by other tests.

The danger of relying entirely upon the indications furnished by the copper test is further emphasized by the fact that other accidental reducing substances, derived from the ingesta, are occasionally found in human urine. For example, chloroform is eliminated with the urine, and such a urine reduces the copper solution. Dr. Sherwin, in a recent number of this JOURNAL, calls attention to the fact that the urine of patients taking chloral will reduce the copper solution. This observation is not, however, a new one, though perhaps not generally known. From the researches of Vetlesen, published in 1882, it appears that during the internal use of oil of turpentine the urine contains a substance which reduces both the salts of bismuth and those of copper. According to Fleischer, the urine of persons taking salicylic acid, or its sodium salt, frequently has all the characteristics of urine containing Boedecker's alkapton.

There are, very likely, several other substances the administration of which may occasionally become sources of error if reliance is placed on the copper test alone. Those mentioned are, we believe, sufficient to show that caution is necessary in making a diagnosis of diabetes mellitus upon an insufficient examination.

#### OIL OF TURPENTINE IN CHRONIC CATARRHAL AFFECTIONS.

THE attention of the profession is again called to the great remedial value of oil of turpentine in chronic affections of the lungs and bowels, this time by Dr.

<sup>1</sup> Journal, December 30th, 1886, January 27th, 1887.

James B. Walker.<sup>1</sup> Turpentine taken internally, he thinks, is capable of impressing almost the entire mucous surface of the body; the exceptions are the uterus and vagina. Its first effects are upon the gastro-intestinal tracts before absorption; and being eliminated by the kidneys and lungs, it physiologically stimulates, and in pathological states, it may favorably modify these emunctories.

Limiting his observations to chronic catarrhal affections of the alimentary and pulmonary tracts, Dr. Walker finds that in hemorrhages from these surfaces it possesses peculiar powers. This is especially true of the stomach, in ulcers of whose mucous coat it stands preëminent. In hemorrhage of the intestines, it is only a little less valuable, and even here it ranks with any other styptic and outranks most of them. It is applicable to hemorrhages of the earlier, as well as the latter, stages of typhoid fever.

In sub-acute and chronic diarrhœas, this remedy, Dr. Walker says, is used to a much less extent than its efficacy deserves. He has seen diarrhœas checked by it, which had for months resisted bismuth, opium, nitrate of silver, sulphate of copper, the mineral acids and other astringents. In chronic diarrhœas, he does not regard bismuth as so serviceable as in acute disease, its value in fact being in inverse proportion to the chronicity. Opium, in these cases, by lessening peristalsis, will arrest the diarrhœa, only to be followed, on its cessation, with an aggravation of the trouble. Lead and silver salts serve to arrest the catarrhal conditions and favor repair, but their influence must be slight in the small quantities which can be safely administered, and in view of the extensive surface upon which they must be distributed to be of any avail. Besides, in most of these cases the diseased areas are more or less protected by a tenacious environment of mucus. Turpentine may be given in considerable quantities without fear of irritation, and its volatile nature enables it to diffuse itself throughout the bowel, into all the intestines thereof, and to permeate even the mucous environment of the diseased glands, and directly impress these structures.

The best time for giving turpentine is between meals, and at bedtime. If, however, when taken on an empty stomach, there is much regurgitation, it should be administered about an hour after a meal. The oil may be given in gelatine capsule, each capsule inclosing from five to ten drops. In this form the drug is not tasted unless regurgitated; and if taken an hour after meals, will be so quickly passed into the intestines as to interfere little if at all with gastric digestion. Where the patient cannot swallow the capsules, the turpentine may be given in some sweetened emulsion, well flavored with anise or wintergreen.

In chronic bronchial affections, oil of turpentine has been found equally serviceable, and Dr. Walker states the proposition that in proportion to the chronicity of the bronchial catarrh, ammonia becomes of less, and turpentine of more value. He has used the turpentine

with signal success, not only in catarrhal conditions secondary to acute disease, but in primary catarrhal diseases which linger and threaten to involve the alveoli, or have already involved the alveoli and become entitled to classification as incipient phthisis. In the dry form the drug has not seemed desirable, but in the form characterized by decided or abundant expectoration its best effects are obtained.

The method of administration may be varied. Terrebene is an exceedingly good preparation, which may be less offensive to some patients than the crude oil. Dose, five to ten drops, on sugar, in emulsion, or in capsules. Or the oil of turpentine may be given in the same way. In bronchial catarrh turpentine is sometimes given in the form of tar (by inhalations or by mouth) and the following is a favorite formula of Dr. Walker:

R	Animon. Chlorid.	. . .	3 iss.
	Vin. picis liquid.	. . .	3 ss.
	Syr. Tolu.	. . .	f 3 i.
	Aquæ.	. . .	f 3 iss.

M. Sig. A desert spoonful every four hours.

Bedford Brown, in the Journal of the American Medical Association (September 25th, 1886), advocates the use of turpentine in the management of the more painful affections of the alimentary canal in infants and young children. According to his experience, the oil of turpentine fills a place which no other remedies can fill. He believes the therapeutic effect of turpentine to be of multiform character. "It is eminently soothing to the irritated and inflamed mucous membrane, and seems to promptly arrest the rapid exfoliation of epithelium. It is antifermentative, deodorant and antiseptic." He lauds the beneficial action of turpentine in gastralgia, intestinal catarrh, enteritis, and a number of unclassified painful affections of a functional kind. He prescribes turpentine according to the following formula:

R	Mucilag. acacie	. . .	f 3 iss.
	Sodæ bicarb.	. . .	gr. x.
	Chloroform.	. . .	gtt. x.
	Ol. terebinth.	. . .	3 ss.

M. Sig. A teaspoonful every two or three hours to an infant of six months.

#### THE REPORT OF THE SUPERVISING SURGEON-GENERAL OF THE MARINE HOSPITAL SERVICE.

In the operations of this Service our government approaches the paternal more nearly than in any of its branches, unless, perhaps, in the care of such of its wards, the original inhabitants of the soil, as it has ceased to treat as foreigners.

It used to be a matter of ever-recurring surprise that fishermen were not eligible to the benefits of the Marine Hospital Service. The matter was simple enough; only those were entitled to relief from the Marine Hospital fund who had contributed to it. The Service is now supported from the tonnage tax, rather than from individual assessments; and as fishing-vessels pay tonnage tax, by a decision of the Treasury Department, "seamen employed on vessels licensed

<sup>1</sup> Medical and Surgical Reporter, January 8, 1887.

for the fisheries are entitled to the benefit of this Service." Previous to this decision, even those engaged in whaling were ruled out of the marine hospitals.

This department still needs what has been so repeatedly asked for, a national refuge for decrepid seamen, and those suffering from incurable affections. The Surgeon-General suggests that if such a "snug harbor" were established in the District of Columbia, it could also serve as the general headquarters of the Bureau, and for the laboratory, purveying division, etc. Better accommodations would add greatly to the efficiency of the purveying department.

A large portion of the report is occupied with the quarantine service, and the reports of the medical officers engaged in it. It is believed that no case of small-pox was admitted into the United States across the northern border during the time of the quarantine established to prevent such an invasion.

Stubborn resistance to vaccination was occasionally offered by a car of immigrants, or by a few passengers in the parlor-cars. At many towns in Canada, certificates of vaccination were sold by physicians, or persons claiming to be physicians, to persons who had not been vaccinated, to enable them to pass the United States sanitary inspectors. Out of one party of forty immigrants provided with certificates of vaccination, examination showed that but seven had ever been vaccinated. This party had purchased their certificates for twenty-five cents apiece. The compulsory vaccination of passengers by the United States was a material aid to the Canadian authorities in carrying out sanitary regulations in the Provinces.

The report contains the usual statistical tables, and many valuable reports of cases and autopsies, and, in addition, a *résumé* of the conclusions adopted, and of the propositions rejected by the Technical Commission of the International Sanitary Conference of Rome (1885).

#### MEDICAL NOTES.

— From the report of the City Registrar of Providence, R. I., it appears that there were 2,355 deaths in Providence during the year 1886. This number was 191 more than in the previous year, and calling the population of the city 120,000, the rate of mortality was 19.62 in each 1,000 of the population. The number of deaths, in 1886, was greater than was ever before reported in Providence for a single year.

— To the suggestion of the *Medical and Surgical Reporter* that each of the eighty thousand physicians in the country ought to contribute fifty cents towards a memorial to Dr. Rush, the *American Lancet* replies that more than half that number had better use their fifty cents to pay their debts, provide for their families, or secure much-needed aids and appliances for the practice of their profession. It considers the majority of doctors ought to scrutinize even so small a

coin as a half-dollar before applying it to so sentimental a purpose as a memorial.

— The *London Medical Record* quotes Dr. Lahrie to the effect that repeated painting of the throat with a five per cent. solution of cocaine has caused an immediate lessening in the number of attacks of whooping-cough, children having fifteen or twenty attacks in the twenty-four hours only having five to ten attacks after the application. As the topical effect of the drug is of short duration, it is necessary to repeat it fairly often, but no tolerance is established, as with other drugs. Improvement took place in the general health, probably due to the diminution in the cough.

— The death of Lord Iddesleigh, better known by the name Sir Stafford Northcote, under which he gained his high political reputation, was traced to his great labors, and possibly, disappointments in public affairs, with the late hours incidental to Parliamentary business. In 1882 he was obliged to cease work, on account of evidence of cardiac mischief; evidence which had presented itself in a less pronounced form many years before when he was quite a young man, and on account of which he was advised to abstain from a parliamentary career. His sudden death occurred in Downing Street, in the presence of Lord Salisbury, whither he had gone to turn over the affairs of the foreign office to his successor. There was disease of both the mitral and aortic valves, but the failure of the latter was the immediate cause of death.

— Cases have been reported in which syphilis has been communicated through the Jewish ritual of circumcision from mucous plaques in the mouth of the operator. A Vienna correspondent of the *New York Medical Journal* refers to an epidemic of tuberculosis of the inguinal glands, originated among Israelitish children by a Jewish rabbi who had a tuberculous ulcer of the tongue. These cases were communicated by Professor Bergmann to the last Congress of Surgeons at Berlin. As a supplement to these cases, Professor Hofmokl presented to the Society of Physicians a child eight months old, who had been under his treatment six months before. The child had been circumcised, as usual, on the eighth day, and bleeding had been stopped by the operator taking the penis into his mouth. The wound did not heal, and seven weeks afterwards, a small gray ulcer was seen on the dorsum penis and remnant of the prepuce, accompanied by swelling of the glands in both groins. There were no manifestations of disease in other parts. The administration of iodide of potassium and of mercury in various forms, together with the application of iodoform locally, had been of no avail. The inguinal glands continued to swell, and some of them suppurated. The ulcer on the penis grew larger. No tubercle bacilli had been found in the pus, and there were no signs of syphilis. On the day after he was shown to the Society the child was put under chloroform, and

thirty glands, which had undergone partly caseous and partly suppurative changes were removed from the groins. Paquetin's cautery was applied to the ulcer. The removed glands proved to be tuberculous, and tubercle bacilli were found in them by Professor Weichselbaum. The mother of the child and its nurse were healthy.

## BOSTON.

— A bill has been introduced in the Massachusetts Legislature to restrict the sale of "Rough on Rats."

— A female school-teacher in Taunton, Mass., punished a seven-year old pupil for whittling his desk by "whittling his finger," deliberately cutting the thumb with a knife till she drew blood.

— Through the admirable activity of Dr. Henry I. Bowditch, the Boston Relief Committee have voted to appropriate \$5,000 to the restoration of the Medical School and the Roper Hospital of Charleston, S. C.

— The remarkable history of the poisoning by Mrs. Sarah Jane Robinson, of Somerville, of her children and others, in whose death she had a personal and pecuniary interest, has already been referred to in these columns, and is fresh in the minds of our readers. A seventh probable victim has now been discovered. The body of Oliver Sleeper, of Cambridge, which was recently exhumed from Mount Auburn Cemetery, owing to suspicions that he was another victim of Mrs. Robinson, has developed the existence of arsenic. The quantity found was about the same as discovered in the other cases. It is presumed that the investigation will now go back still farther, and that the body of her brother-in-law, Mr. Field, of Chelsea, with whom Mrs. Robinson lived at one time, will be the next to come under examination. It is reported that the physician who attended Mr. Field has said that his symptoms were those of arsenical poisoning.

— A series of suits for damages was recently decided in the fourth session of the Superior Civil Court, Boston, before Judge Pitman. The cases are of great interest to physicians, as well as to landlords and tenants. The suits were brought to recover damages for sickness and costs of medical attendance, caused by alleged defective drainage. The plaintiff, Charles A. Cutter, leased a house of the defendant at No. 60 Allen Street, Boston, with the representation that the drainage was in good condition. Mr. Cutter set forth that, owing to the bad drainage, he and other members of his family had diphtheria, one child dying thereby. The defendant denied his liability, and, in defence, claimed that the drainage was good. The suits were in the names of five members of the Cutter family, and ended in substantial verdicts for the plaintiffs, the amounts being, respectively, \$1,600, \$700, \$300 and \$250 each in the last two cases, making a total verdict of \$3,100.

## NEW YORK.

— Mr. Ernest Crosby, son of the Rev. Dr. Howard Crosby, has introduced into the Legislature a bill re-

organizing the City Board of Health, which has been drawn up by Mr. James Gallatine, who has paid much attention to the workings of the Department. It abolishes the commission which now manages the affairs of the Board, and substitutes therefor a single Commissioner of Health, who shall hold office for six years, receive a salary of \$8,000, and be appointed by the Mayor, the latter being authorized to remove him also "for reasons to be stated in writing and published in the *City Record*." Except as otherwise provided in the act the powers, authority, and duties of the commissioner shall be the same as those of the present Board. He shall appoint a Deputy, at a salary of \$5,000, who may act as Commissioner for a period not exceeding three months. All the duties of the present Secretary of the Board are conferred upon this officer. The bill abolishes the office of Attorney and Counsel to the Health Board, and authorizes the Corporation Counsel to assign an Attorney to the Department. The clerks and other employees of this attorney shall also be appointed by the Corporation Counsel. For the payment of the salaries of the Attorney and his employees a sufficient amount of the appropriation for the Health Department for the year 1887 shall be transferred to the credit of the Law Department.

## Correspondence.

## MILKY TUMORS OF THE AXILLA.

LONDON, 6 Nottingham Terrace,  
YORK GATE, N. W., January 21, 1887.

MR. EDITOR.—Your correspondent, Dr. Edward T. Williams, writes on December 16th, 1886, in your JOURNAL, on the above subject, that Dr. Champney is mistaken in supposing that he was the first to describe certain lumps in the axilla of lying-in women.

In proof of this he refers to the Sydenham Society's Translation of Velpeau's "Diseases of the Breast," pp. 233-235, where Velpeau "cites five cases by Scarpa, Siebold, Moor, Lee and Stanley (with references), which seem to have been quite similar to those described by Drs. Champney, Johnson, and Sinclair. Siebold's case, in particular, appears to have been the exact counterpart of Johnson's."

I think that Dr. Williams cannot have read Dr. Champney's paper, and compared the cases described by him with the originals of those quoted by Velpeau.

The majority of Dr. Champney's cases of "axillary lumps" having fallen under my personal observation, I may state that the characters which they presented by no means tally with the original descriptions of the five cases quoted by Velpeau.

(1) *Scarpa's* case was simply a case of large galactocoele, and has nothing to do with Dr. Champney's "axillary lumps."

(2) *Siebold's* case<sup>1</sup> presents some points of resemblance to Dr. Champney's cases, but there is no exact note either as to the precise situation of the tumor or as to the places from which the milk exuded (in Dr. Champney's cases the lump was invariably situated at the apex of the axilla and in the portion of skin covered by hair, and, though not necessarily commensurate with it, never extending beyond it, and the milk exuded on pressure from the roots of the hairs all over the lump). Moreover, the pendulous state

<sup>1</sup> Berl. Med. Zeitung, No. 6, 1838.

which the lumps eventually assumed, "hanging down an inch," is unlike any of those described by him.

This case may possibly have been of the same nature, but from Siebold's description it cannot be proved.

(3) "Moore's case" is a plain case of right axillary mamma with several nipples.

(4) Lee's case is one of bilateral axillary mammae with nipples.

(5) Stanley's case is very imperfectly reported, but appears to be one of axillary mamma with pores or ducts.

So far for Dr. Williams' "quite similar cases."

No one ever supposed that Dr. Champney claimed to be the first to describe "milky tumors of the axilla," but it has yet to be proved that the lumps which he has described have been noticed as such before his paper appeared.

Very truly yours, ROBERT BOXALL, M.D.

<sup>1</sup> W. H. Moore. *Lancet*, February 24, 1838, p. 786.

<sup>2</sup> Dr. Robert Lee. *Med. Chirur. Trans.* for 1836, p. 266.

<sup>3</sup> *Lancet*, 1838, p. 642.

# THE DOCTOR'S MESSAGE TRANSLATED.

SALEM, February 4th, 1887.

MR. EDITOR, — B's Greek is, *en anglais*, "My folks want me to go home." S. F. Q.

MR. EDITOR, — B's patient desired to tell his physician that his family wanted him to go home (*ol ávaykáia, necessarii*, those who are necessary to one, that is his kinsfolk). If the writer was a college student there would seem to be a peculiar fitness in his use of the word, the *necessarii* being the ones who furnish the *necessaria*.

Yours truly, Z.

MR. EDITOR, — The slight remains of my classical education would have led me to believe that the patient meant to say "necessity calls me home." Y.

Deaths reported 2,022: under five years of age 699; principal infectious diseases (small-pox, measles, diphtheria and croup, erysipelas, fevers and diarrhoeal diseases) 299, acute lung diseases 377, consumption 255, diphtheria and croup 130, measles 64, diarrhoeal diseases 30, typhoid fever 21, scarlet fever 25, malarial fever 14, whooping-cough nine, erysipelas six, cerebro-spinal meningitis seven, small-pox (New York) three. From scarlet fever, New York 16, Philadelphia five, Boston two, District of Columbia and Lynn one each. From malarial fevers, New York four, Baltimore, New Orleans and Lowell three each. From whooping-cough, New York three, Philadelphia and Pittsburgh two each, District of Columbia and Nashville one each. From erysipelas, Boston three, New York two, Salem one. From cerebro-spinal meningitis, New York five, Fall River and Taunton one each.

In the 21 cities and greater towns of Massachusetts, with a

population of 989,182 (population of the State 1,941,465) the total death-rate for the week was 22.46 against 20.74 and 22.02 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,245,098, for the week ending January 15th the death-rate was 24.1. Deaths reported 4,362: infants under one year of age 866; acute diseases of the respiratory organs (London), 591; measles 195, whooping-cough 95, scarlet fever 82, fever 48, diarrhoea 34, diphtheria 31.

The death-rates ranged from 17.4 in Portsmouth to — in Wolverhampton; Birmingham 22.8; Bradford 30.8; Huddersfield 23.8; Hull 22.8; Leeds 28.6; Liverpool 28.2; London 23.0; Manchester 31.0; Newcastle-on-Tyne 27.9; Nottingham 20.9; Sheffield 22.4.

In Edinburgh 20.8; Glasgow 31.0; Dublin 36.2.

The meteorological record for the week ending January 29, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending	Barom- eter.	Thermometer.			Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM JANUARY 29, 1887, TO FEBRUARY 4, 1887.

**POWELL, JUNIUS L.**, captain and assistant surgeon. Granted leave of absence for two months, to take effect when his services can be spared by his department commander. S. O. 24, A. G. O., January 29, 1887.

**CLUNDENIN, PAUL**, first lieutenant and assistant surgeon. Ordered for duty as post-surgeon at Camp Pena Colorado, Tex. S. O. 14, Department of Texas, January 26, 1887.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE HOSPITAL SERVICE FOR THE SIX WEEKS ENDING JANUARY 29, 1887.

**WYMAN, WALTER**, surgeon. Granted leave of absence for three days, January 14, 1887.

**WHEELER, W. A.**, passed assistant surgeon. To proceed to Erie, Penn., as inspector, January 12, 1887.

#### SOCIETY NOTICE.

**SUFFOLK DISTRICT MEDICAL SOCIETY. OBSTETRIC AND GYNECOLOGICAL SECTION.**—There will be a meeting of this Section at the large Medical Library Room, 19 Boylston Place, on Wednesday evening, February 16th, at 7.45 o'clock. Communications: Dr. H. O. Marcy, "The Perineum: Its Functions and Restoration. Illustrated by Stereoscopic Projections." Dr. J. B. Swift, "A Case of Alexander's Operation."

JAMES R. CHADWICK, M.D., Chairman.

ROBERT B. DIXON, M.D., Secretary.

#### OBITUARY.

##### CRIDLAND CROCKER FIELD, M.D.

Dr. Cridland Crocker Field, of Eastern Pennsylvania, died at his home the last of November, aged nearly seventy, of neuralgia of the heart. He was widely known in his neighborhood and even outside his State as a surgeon, and had been in active practice nearly fifty years. Among the operations which gave him a reputation were the removal of a cervical tumor, with ligation and excision of a considerable part of the jugular vein; excision of the entire femur; excision of the entire radius; extirpation of the parotid gland, which difficult operation he has performed several times. His favorite region for operating was the neck, from which he has time and again removed tumors, which had entirely encompassed the carotid artery. He enjoyed a large consultation practice and came of a medical family both his father and grandfather having been in the profession, the former a member of the Royal College of Physicians of London.

##### DR. JOSEPH T. O. WEST.

The President of the Massachusetts Medical Society, Dr. Thomas H. Gage, at the recent meeting of its Councillors, announced the death of Dr. J. T. O. West in the following just and appreciative words: Dr. Joseph T. O. West, of Princeton, died after a brief illness on the 28th of January. A severe and distressing attack of laryngitis, with which he was seized on the 9th, was followed by pneumonia, nephritis, uræmic coma, and death.

The deceased was born in Barnstead, N. H., on the 21st of June, 1823. He was fitted for college at the high school in Lowell, and graduated from Dartmouth in the class of 1845. His professional studies were pursued under the direction of Dr. Nathan Allen, of Lowell, and he received his medical degree from Harvard in 1848. Subsequently, he practiced for a time successively in Holden, New York City and Lowell, removing from the latter place to Princeton in the autumn of 1854. There he remained, the sole medical occupant of the field, to the time of his death.

Dr. West's was a rare and beautiful character, and one that might properly receive a more extended notice than I can give it here.

To great natural abilities, trained, disciplined, and educated in the schools, he added high professional attainments, and the richer graces of a pure and consistent Christian life. And such natural endowments and acquirements, an intelligent and discerning people were not slow to recognize and appreciate. Thus it came about that early in his life, and to the end, he was respected, trusted, honored and beloved, as it falls to the lot of very few to be. Both profession and lady gave him, without reserve, their confidence and regard.

As a physician he was remarkably modest and unpretending, yet judicious and skilful, and equal to any emergency. High professional attainments and skill, and the wisdom gained by experience, he held as sacred trusts, to be administered under a sense of great accountability, and he was faithful to the solemn charge.

In his death, the community he had served so long, faithfully and well, and the transient summer visitors that throng the Princeton Hills, have sustained a great and irreparable loss. He was for more than thirty years their trusted medical adviser, their wise counsellor in times of trouble, and their friend; and it was a touching scene as the stricken people, yesterday, moving in mournful procession, and in grief and tears, laid him under the shadows of the great mountain, tenderly at rest.

##### DR. LUTHER MARTIN KNIGHT.

Dr. Luther Martin Knight, of Franklin Falls, N. H., died of chronic hepatitis, February 4th (?), aged seventy-seven years. He was born in Franconia, N. H., graduated from the Dartmouth Medical College, practised in Thornton for ten years and in Franklin forty-two years. He was surgeon of the Fifth New Hampshire Regiment in the Rebellion, afterwards chief of the medical staff of the Second Army Corps under General Hancock. He represented Franklin in the Legislature in 1854 and 1856, and has been president of the New Hampshire Medical Society. He leaves a widow and four children.

#### BOOKS AND PAMPHLETS RECEIVED.

Twelfth Report of the Salem Hospital. Salem, 1887.

President's Address. Tenth Annual Meeting of the Detroit Medical and Library Association. By C. J. Lundy, A.M., M.D. 1886.

The Medals, Jetons and Tokens Illustrative of Obstetrics and Gynecology. By Horatio R. Storer, A.M., M.D., Newport, R.I., 1887. (Reprint.)

Report of the Board of Trustees of the Eastern Michigan Asylum, at Pontiac, for the Biennial Period ending September 30, 1886. Lansing. 1886.

## Lecture.

### MULTIPLE NEURITIS AND ITS RELATION TO CERTAIN PERIPHERAL NEUROSES.<sup>1</sup>

BY M. ALLEN STARR, M.D., PH.D.,  
Professor of Nervous Diseases, New York Polyclinic.

AN etiological classification of the cases of multiple neuritis appears to be the one most useful to the clinical observer, and as the forms vary considerably in their symptoms, we shall perhaps arrive at a more definite knowledge of the disease if we consider each of the classes separately. It is possible to distinguish

I. Toxic cases, due to poisoning by alcohol, arsenic, lead, and bisulphide of carbon.

II. Infectious cases, due to the direct action upon the nervous system of the infectious agents, producing diphtheria, variola, typhoid and typhus fevers, severe malarial fevers, and tuberculosis, to which must be added the agent causing the epidemic form of neuritis known as kakke or beriberi.

III. Spontaneous cases, due to uncertain causes, among which cold and exposure to damp and wet, and to over-exertion, may find a place.

#### I. TOXIC CASES.

(a) *Multiple neuritis, due to poisoning by alcohol.* While alcoholic paralysis has been universally recognized for many years, it is only within a short time that the symptoms and pathology have been brought into a logical connection.

All observers have emphasized the fact, already noted by Jackson, that the disease is especially frequent among females. Males are not, of course, exempt from alcoholic paralysis, but, in them, the poison seems more liable to manifest itself by acute cerebral symptoms than by those of disease of the peripheral nerves. It is especially frequent among those persons in the higher classes whose nervous organism is highly developed, and who lead a comparatively inactive life. It seems not at all improbable that sedentary habits predispose an alcoholic drinker to this disease, and hence active workers, male or female, though taking an equally large amount of liquor as the luxurious drinker, escape. All alcoholic drinks are not equally prone to produce paralysis. It is the spirituous liquors — brandy, whiskey, gin, and rum, and the liqueurs, absinthe, vermouth, etc. — which are dangerous. And it is only after these drinks have been consumed in large amounts, and for a considerable length of time, that neuritis develops. Its onset, though often apparently very sudden, is usually gradual. For months the patient has suffered from chronic gastritis, insomnia, general neuralgic pains, or severe pains in the joints or limbs, and from tremor and a certain feebleness in movement, when all at once her legs give way beneath her, and after the sudden fall she finds herself unable to rise. Thus a patient of my own, after a year of such premonitory symptoms, was seized with paralysis quite unexpectedly when getting out of bed in the night. This paralysis soon becomes complete in the feet and legs below the knees, and may advance up the thigh. It next attacks the hands and forearms, and while in all extremities, it is often greater in the extensors than in the flexors;

in some cases both groups of muscles become entirely helpless. This has been the case in three patients under my care. The paralyzed muscles are flabby and soon become atrophied, they have no excitability to mechanical irritation, and the tendon reflexes are lost. They fail to react to a faradic current in the majority of cases, though occasionally a very strong current may produce a response. When galvanism is applied, the reaction of degeneration is found to be present. No stimulus can be given to the muscle by sending a current through its nerve, and the positive pole produces more marked contractions with an equal current than the negative pole when placed on the muscle, and then it is only a slow or vermiform movement, not the quick jerk of health. It is also found that strong galvanic currents have to be used to produce any contraction at all. The paralysis of the muscles may advance rapidly in severe cases, involving the motor cranial nerves, the muscles of the trunk, and lastly, the diaphragm, thus causing death. More frequently, however, it is arrested when only the distal parts of the extremities are involved, and then it gradually subsides until recovery is complete. The position assumed by the paralyzed limbs has been thought to be almost characteristic. There is dropped wrist, quite similar to that seen in lead-palsy, and also dropped foot, due to the falling forward of the foot from its own weight, since the anterior tibial muscles are weak. This deformity is increased by the fact that the patients lie in a recumbent posture, with the feet extended; and when the flexors of the toes are but slightly affected, as sometimes is the case, their unopposed contraction serves to exaggerate the malposition. If there is entire paraplegia, the legs and thighs may both be extremely flexed, so that the heels touch the buttocks, but this is exceptional. While the dropped wrist is the usual deformity of the hands, cases are recorded in which the paralysis was limited to single muscles, and to muscles supplied by single nerves.

To the physician, these motor symptoms, and the oedema, occasional lividity, profuse sweating, and glossy skin, so often associated with them, are very noticeable. But the patient suffers far more from the disturbances of sensation. In the description of Jackson, the pains were graphically portrayed. They are the cause of terrible agony, sufficient to produce insomnia, and wearing seriously upon the endurance of the sufferer.

In addition to pain, hyperesthesia is not infrequently observed. It is usually quite extensive in the legs, though in cases of poisoning by absinthe it has been limited to the soles of the feet. The muscles, as well as the skin, are sensitive to handling and to pressure, and marked tenderness in the course of the nerves is always elicited by examination. In one of my cases, soon after the onset, the patient could not bear to be touched or moved, though perfectly unable to help herself. Charcot goes so far as to say that muscular sensitiveness, associated with flaccid paralysis, is pathognomonic of alcoholism.

Paræsthesia are always complained of. Numbness, tingling, and formication are frequent. In one of my patients the sensation was as if heavy bracelets were around the wrists, and as if very tight drawers were on the legs. At other times she felt as if the limbs were swollen, and as if the skin were about to burst. Such sensations may cease as the case increases in

<sup>1</sup> Lecture II of the Middleton Gohlanith Lectures, delivered under the direction of the New York Pathological Society, Jan. 28, 1887. For Lecture I, see page 101 of the Journal.

severity, and gives place to a total lack of sensation in the parts. They return, however, with advancing recovery, and are among the last symptoms disappear.

Abolition of tactile sense, and, to some degree, of muscular sense, is the rule after the paralysis is developed. Temperature-sense and the perception of pain are never wholly lost, but may be delayed in transmission. The anesthesia may be limited to irregular areas, and may be only in the cutaneous distribution of one nerve, but is usually found over the entire distal part of the paralyzed limb. Usually the cutaneous reflexes are preserved. The loss of muscular sense is, in some cases, so marked a symptom, and one of such early occurrence, that Dreschfeld distinguishes a class of cases which he terms ataxic, rather than paralytic. And this distinction is perfectly justifiable, for in many cases it is the incoordination which attracts the attention of both the patient and the physician. It is this class of alcoholic cases which may be mistaken for locomotor ataxia, and which has been named by French writers pseudo-tabes alcoolique. But ataxia is not exclusively limited to this class of cases. Nor are the cases of ataxia, on the other hand, free from paralysis.

And this fact is proven by the observations of Westphal and Charcot. There may be in both patients some tottering and swaying when standing with the eyes closed; the so-called Romberg symptom is common to both locomotor ataxia and alcoholic neuritis.

The special senses are occasionally affected in cases of alcoholic paralysis. Amblyopia has been observed, and also defected vision from central scotoma. The field of color-vision is often contracted, even when sight is preserved. There may develop a true optic neuritis, evident to the ophthalmoscope, and this may go on to optic nerve atrophy.<sup>2</sup> Inequality of the pupils is frequently seen, as is also a moderate contraction of the pupil. All these eye symptoms, occurring as they may in a case of the ataxic variety, make a differential diagnosis from locomotor ataxia difficult. The Argyll-Robertson pupil (which contracts in accommodation but not to light) has not been seen in in alcoholic cases, while it is an early symptom of tabes.

One feature of alcoholic paralysis remains to be noticed, namely, the cerebral symptoms. These are hardly ever wanting. There is at first the excitement rising to the degree of active delirium, with illusions and hallucinations of the various senses; there is the insomnia, which so soon exhausts the patient if it is not remedied; there is the loss of memory, especially of recent occurrences; and the lack of power of attention or concentration, which prevents intelligent conversation. The indifference to bodily wants may be so great as to lead to uncleanness, and since paralysis of the sphincter is the rare exception, incontinence is usually to be ascribed to the mental state. It is useless to attempt to get any reliable history of their illness from these patients. Their statements are unintelligible or unreliable. And here it may be well to notice a symptom first remarked by Strümpell. These patients will relate occurrences as having happened recently, with much elaboration of detail, when, as a fact, the story is entirely a product of their imagination. Thus, one patient of my own, who has

been confined to bed for many days, told me one afternoon that she had been out to see an eminent gynecologist during the morning; had gone to his office and waited for him several hours; had seen other patients there, and finally had been told by the doctor's brother that he would not return in time to see her, so she had come home again. And this was all related in apparent good faith, so that I have no doubt that she believed that what she said had occurred. With the possibility of such delusions in view, it is evident that the statements of these patients cannot be accepted regarding anything, especially as to their own history.

One patient, who was admitted to Bellevue Hospital during my service there, told me a different history of her case, every day for a week; and it was only by interviewing her friends that the correct account was obtained.

The course of alcoholic neuritis is quite uniform. After a sudden onset the symptoms rapidly advance to a high degree, which is reached in a week or two from the beginning of the paralysis or ataxia. Then they may increase further, and cause death by respiratory paralysis. Usually they remain stationary for a time, and then gradually subside, the entire duration being from two months to a year. Individual muscles retain their power, tone, firmness, and electrical reaction slowly, and during recovery the tingling and numbness in hands and feet may be severe. In a few cases the muscles become contracted, and permanent deformities, only to be overcome by long-continued massage, or by operative measures, develop. When the fact is considered that those who recover rapidly, rarely fail to resort again at once to the use of stimulants, and thus expose themselves to the danger of a relapse, the ultimate fate of the chronic cases is hardly more serious than that of those who get well.

Examples of the paralytic form were cited.

(b) *Multiple neuritis due to poisoning by arsenic.* It has long been known that an occasional result of arsenical poisoning is the development of paralysis, but it is only within the past four years that the fact has been determined that the symptoms in these cases are due to an affection of the peripheral nerves. Had the fact of the peripheral origin of alcoholic paralysis not been already proven, it is probable that the theory so long in vogue, that arsenical nervous symptoms were due to spinal lesions, would still prevail. But there is such a similarity between the two sets of cases, that it is impossible to ascribe them to other than the same pathological condition. Autopsies in support of the position that the peripheral nerves are involved, are few in number, but in several cases the lesion has been found. The observations on record of spinal lesions are, it is true, more numerous; but when these are compared it is found that different lesions have been discovered in different cases, so that there is no single pathological change in the spinal cord which is constantly produced by arsenic. Further, some of the changes described in experimental cases in animals (namely, vacuolization of cells) are due to imperfect hardening of the specimens. It must, therefore, be admitted that multiple neuritis may be due to arsenical poisoning.

The changes produced in the nerves are so exactly similar to those already described, that there is no need of a recital of the pathological process.

The nervous symptoms produced by arsenic have

<sup>2</sup> Brissaud, Des Paralyties toxiques, p. 31. Paris, 1886.

been thought to vary somewhat, according as the ingestion of the poison has been a sudden or a gradual one. Briassaud claims that if there is slow poisoning, as for example, by the long-continued use of Fowler's solution, paralysis is rather the exception, and is not severe—it is diffuse and transient; while other symptoms, such as gastro-enteritis, trembling, delirium, and aphasia attract the chief notice. If there is acute poisoning from an overdose of arsenic, he holds, on the other hand, that paralysis ensues either during the period of active symptoms of poisoning, or soon after. The observations of other equally careful authors do not entirely support this view of Briassaud; for in two cases of Dana, one of acute, the other of chronic poisoning, very similar symptoms of paralysis and ataxia developed.

The description which has been given of alcoholic paralysis might almost be repeated for arsenical paralysis. There is the same limitation of the affection to the muscles of the distal parts of the extremities, the extensors being chiefly affected, and the weak muscles are flaccid, soft, and atrophied. There is a partial reaction of degeneration. The tendon reflexes are abolished; skin reflexes are preserved. There is often a marked tremor. The paralysis may begin either in the feet or in the hands, is usually bilateral, but has been in four cases of the hemiplegic type. The same dropped wrist and dropped foot are seen as in alcoholic cases. Disturbances of sensibility are prominent symptoms; burning, tearing, shooting pains; formication, tingling, muscular, and arthritic pains and tenderness are associated with hyperæsthesia, and this may be followed by irregular patches of anæsthesia. The muscular sense is usually impaired, and so much so in some cases that an attempt has been made to establish a distinct class of cases as arsenical ataxia, or pseudo-tabes arsenicale. In these cases the incoordination of hands and feet—Romberg's symptom—and an awkward gait are very noticeable, so that tabes may be suspected until the history makes the causation evident.

(c) *Multiple neuritis due to poisoning by lead.*—It is not my purpose to enter upon any description of the various forms of lead palsy, which are familiar to every practitioner. Nor is this the proper place for a discussion regarding the various theories of the pathology of the disease. It is only necessary to call attention to the fact that there are now on record a number of autopsies in cases of lead paralysis in which the lesion has been found in the peripheral nerves. In a recently published case of Schultze there was found a very marked atrophy and disappearance of nerve-fibres in the trunk of the musculo-spiral nerve, below the point where the branch to the supinator longus was given off. This decreased in intensity centrally, so that at the brachial plexus no anomaly was found. It increased in intensity toward the termination of the nerve in the muscles. The spinal cord was normal. This is simply a type of a number of recently published cases. On the other hand, there are numerous cases of this disease in which decided spinal lesions have been found—so numerous that many writers ascribe the disease always to destruction of certain groups of cells in the anterior cornua of the spinal cord. It must be admitted, therefore, that in lead we have a poison which, under certain circumstances, affects the spinal cord, and under other circumstances produces neuritis.

## II. MULTIPLE NEURITIS CONSEQUENT UPON INFECTIOUS DISEASES.

There are a number of infectious diseases which are especially liable to be followed by the development of nervous symptoms. These are diphtheria, variola, typhoid, typhus, and scarlet fever, malarial fever and tuberculosis. The nervous affection usually appears shortly after the period of convalescence in the acute fever. The disease may consist of a simple paralysis of the muscles in the region of distribution of a single nerve. It may affect several nerves on both sides of the body symmetrically. It may even paralyze two or more limbs. It occasionally produces sensory as well as motor symptoms in a single nerve-trunk. It may even cause a general sensory and motor paralysis of as widespread and complex a kind as that produced by chronic alcoholism. Sometimes the symptoms are chiefly of a sensory kind, and consist exclusively of pains, numbness and anæsthesia, or hyperæsthesia, in the legs, or of a loss of the muscular sense, in which case a true ataxia is the most noticeable symptom. Thus it is evident that the poison of an infectious disease may act as powerfully upon the nervous system as any other form of poison known.

It is only since the clinical pictures presented by multiple neuritis have been recognized that a question has arisen as to the part of the nervous system affected in these cases. Formerly all such phenomena were referred to central lesions; and undoubtedly in many cases this was justified, since autopsies are not wanting to prove that anterior poliomyelitis, diffuse myelitis, and hæmorrhages into the cord and brain may follow the acute fevers. There are, however, many conditions which do not correspond to the types of disease produced by central lesions, and which recover with a rapidity impossible were the brain or spinal cord involved. It was these cases which raised the question of some possible affection of the peripheral nerves. And careful investigation has been rewarded by the actual discovery of lesions in them.

(a) *Diphtheritic paralysis* is probably more common than any other of these forms of neuritis. As is well known, it is usually the soft palate to which the paralysis is limited, and, as a result, difficulty in swallowing and in speech are the most prominent symptoms. Bernhardt has found that in the large majority of cases of this kind there is a loss of the patella tendon reflex, but whether this indicates any general affection of the peripheral nerve he does not venture to state. The limitation of the paralysis to the palate has been explained by supposing that the poison of the disease has a direct action upon the terminal filaments of the nerves, which, in this position are, as it were, dipped constantly in the poison. This theory is supported by a case in which paralysis of the abdominal muscles was associated with diphtheritic inflammation of the navel in a new-born child. But the more serious cases prove that through the blood the poison may be carried to nerves far removed from the seat of the diphtheritic inflammation.

The prognosis in cases of diphtheritic paralysis is usually very good, the fatal cases here cited being rarities. The treatment consists in general tonic medicines, and the application of electricity to the limbs in the same manner as in other cases of neuritis.

(b) *Neuritis following variola* is a rare complication, and but one, the following case, is the only one

on record in which an autopsy proved the seat of the lesion.

*Observation XVII.*—A young man had varioloid in November, 1881, and while convalescing, six weeks later, began to suffer from severe pains in his four extremities, especially in the joints of his arms, which were diagnosed as rheumatic, although there was no fever. Soon after there followed a true paresis, with progressive atrophy of the muscles of forearms and legs. The muscles at the same time became very tender to touch or pressure. The tendon reflexes were much diminished. Reaction of degeneration developed in all the parietic muscles. The pains in the joints and limbs continued, but were less severe than at the outset. The sensibility of the skin was about normal. The nerve-trunks were tender to pressure. Profuse, offensive perspiration in all four extremities was a distressing symptom. There was no tendency to bed-sores, but an extensive pemphigus developed in the legs, and then the pains became more severe. The patient died in July, 1882, of pneumonia.

Autopsy showed the brain oedematous, and the cord in a state of hypostatic congestion. The pathological changes of importance were found in the nerves and muscles. The majority of the nerves of all the extremities were found in a state of degeneration and atrophy. There was marked degenerative atrophy and fatty degeneration of the muscles.

(c) It is still somewhat a matter of conjecture whether cases of paralysis following typhoid, typhus, and malarial fevers, are due to an affection of the peripheral nerves or of the spinal cord. The researches of Pitres and Vaillard\* have shown that extensive degeneration of peripheral nerves is to be found in the bodies of patients who have died of typhoid fever, and they have also demonstrated that these fevers are often followed by local neuritis as a sequel. Cases of multiple neuritis with autopsies have not as yet been reported after typhoid or typhus; but Bazzard has recently recorded† two cases, following malarial fever, in which all the symptoms pointed to an affection of the peripheral nerves. In this country Gibney has described several cases of paralysis of the extremities, of sudden onset, rapid course, and prompt recovery under large doses of quinine, which he considered malarial.

(d) We come, lastly, to those cases of multiple neuritis which occur in tubercular patients, or in those who have had syphilis. If a review of the cases of multiple neuritis already cited be made, it will be found that quite a number of the patients died of phthisis. This was true of the cases of Joffroy, Eisenlohr, Strümpell, Webber and Müller. Oppenheim has reported cases of multiple neuritis in tubercular patients, which went on to recovery.

Although syphilis has been described as a cause of neuritis, I cannot find that the lesion in the few cases examined has had the peculiar characteristics of syphilitic lesions elsewhere in the body, and therefore it seems to me doubtful whether we are justified in describing a syphilitic multiple neuritis. Further facts are needed to establish its existence.

(e) It only remains to consider briefly the epidemic form of multiple neuritis, and our study of the infectious cases will be complete.

In 1882, Professor Scheube, of Tokio, Japan,

called the attention of European physicians to the existence of a peculiar affection prevailing among the Japanese. It was called kakke; from two Chinese words, *kiakke*, meaning legs, and *ke*, meaning disease. It had been known among the Chinese for centuries, being mentioned by name in Chinese medical books written two hundred years before the birth of Christ, and fully discussed by an eminent author in 640 A.D. It ceased, however, to prevail in China about two hundred years ago, and its ravages are now confined, according to Scheube, to Japan. There its importance is considerable, since it is so prevalent that in 1877, fourteen per cent., and in 1878, thirty-eight per cent., of the men serving in the army, suffered from it. It is considered a miasmatic infectious disease by Scheube, although an eminent Japanese authority considers it due in some way to the diet of rice. That diet has something to do with its occurrence is proven by the fact, communicated to me by Dr. Wallace Taylor, that since wheat has been substituted for rice in the diet of some of the barracks and prisons in Japan, the disease has been less common. It occurs in epidemics, but is always endemic in Japan. It does not attack Europeans. It affects females rarely, only nine per cent. of the cases being in women; and it is the youth of the land, between the ages of sixteen and twenty-five, who are attacked. Exposure to damp and cold in crowded dwellings, such as barracks, increases the liability to the affection. The majority of the cases occur during the hot months, but some are always under observation. This disease is not, however, confined to Japan. It has been observed for many years in the islands of the Pacific Ocean, in India, Ceylon, on the west coast of the Red Sea, in Borneo and New Guinea, in Brazil and Cuba, and its prevalence in the Dutch possessions in the China Sea has made it familiar to physicians from Holland who have visited these colonies. It is there known under the name of beriberi. It is endemic in these regions, but occasionally occurs as an epidemic. An interesting account of such an epidemic, occurring in 1882-83, in Manila, the chief city of one of the Philippine Islands, has been given by Dr. Koeniger. It appears that in the fall of 1882 an epidemic of cholera occurred in Manila, of such severity, that twenty thousand persons, in a population of four hundred thousand were affected. As a precaution against this disease, the native population lived for several months almost exclusively upon rice, refusing to eat fruit or fish, which are their other chief articles of diet. As the epidemic was subsiding, a terrible cyclone devastated the city, destroying the light wooden houses, and leaving sixty thousand families homeless; and these poor people were exposed for several weeks to the inclemency of the weather, which at this time of the year is rainy. A few days after the cyclone, the epidemic of beriberi began, and as the disease had never before appeared in Manila, the unknown affection excited great alarm. This was increased by its fearful mortality, sixty per cent. of the early cases proving fatal. Europeans were exempt, with two exceptions, and the Chinese population did not suffer greatly, but among the natives the epidemic was widespread. Thus, in one suburb of Manila, of twenty-five thousand inhabitants, three hundred died in the course of eight weeks. Men and women were equally affected, and persons of all ages, except young children, were attacked. The disease terminated fatally in from ten

\* *Rev. de Méd.*, 1884, p. 980. Des Névrites périphériques.

† *Paralysis from Peripheral Neuritis*, p. 104.

days to five weeks after its onset; but as time went on the proportion of recoveries increased, and by the end of March, 1883, it had almost disappeared. The months from October to March are the dry, cool season in the Philippine Islands, although the climate is tropical. Exposure to heat could hardly be considered a cause of this epidemic, but whether the exposure to cold and damp, or the diet of rice, or the transportation of some infectious agent by the cyclone was the cause, gave rise to much discussion, and could not be determined.

Sporadic cases of beriberi, or kakke, occasionally appear in our hospitals, usually on the persons of Chinese or Malay sailors, or on the persons of travelers from tropical climates, who have been exposed to the infection in the place from which they came. Three such cases have recently been reported by Dr. Seguin, of this city, in patients who came from the West Indies, and a case observed in Bellevue Hospital, by Dr. J. West Roosevelt, was discussed in the Academy of Medicine recently. In 1881, a Brazilian naval vessel entered San Francisco with a large number of the crew affected by the disease. They were sent to the United States Marine Hospital, and attended by Dr. Hebersmith, who gave an interesting account of the circumstances leading to the development of the disease, in the United States Marine Hospital Report.

Only last year a commission was appointed by the Dutch Government to investigate the subject of its nature, and the recently-published report contains the following statements: The disease is caused by a microorganism resembling the bacillus of splenic fever, though somewhat smaller, which color with fuchsin and gentian-violet, and can be seen with a power of 560 $\times$ . These bacilli are found in the blood, lungs, heart, brain, cord, and nerves of the patients, and can be cultivated outside of the body. The germs infect wooden dwellings chiefly. They may be conveyed by articles of clothing, and probably enter the body by the lungs. Direct contagion has not been observed. A potent predisposing cause to their reception in the body and to the development of the disease, is lack of nutrition consequent upon exposure to damp and to cold, and upon insufficient or bad food. It must, however, be added that a most thorough examination in Dr. Roosevelt's case, by Dr. Prudden, failed to reveal the presence of such bacilli.

In the light of these recent investigations, a new view is taken of an epidemic of a peculiar kind which occurred in France in 1828. Buzzard has found an account of this, prepared by Graves, in which the symptoms are so fully detailed as to leave no doubt that it was an epidemic of multiple neuritis.

The cases of beriberi are divided into two general classes, according to their severity.

There are, first, slight cases, in which the onset is gradual, being usually preceded by a little fever, coryza, and conjunctivitis, which cease when the actual symptoms commence. The patient first notices a weak and heavy feeling in his legs, and finds that he tires so easily that he cannot walk as much as usual. The tired feeling is soon associated with numbness and pain in the legs, and with a slight edematous swelling. Then, if not before, palpitation of the heart, oppression and weight in the epigastrium, loss of appetite, and general malaise are felt, and the patient finds it necessary to apply for treatment. An examination

then shows some diminution of power in the feet and legs, and also in the hands, with loss of tendon reflexes, and much tenderness in the muscles, which show a diminished electric excitability. There is never any ataxia, though the patient sways when his eyes are closed. There is discovered a slight degree of anesthesia, of irregular distribution, chiefly in the legs and in the radial-nerve region on the forearms. Though the patients look pale, it is usually impossible to find anemia by examination of the blood. The circulation in the extremities is sluggish. The heart is irregular and rather rapid, and the edema of the extremities indicates a failure of its power. Dr. Wallace Taylor finds that a sphymographic tracing is characterized by a sudden high upstroke in ventricular systole, by a precipitous descent from the apex of the percussion wave, and by diastolic. Beyond this point, these cases, which make up the majority, do not advance. They usually recover in a few days, or, at most, a month, although a few become chronic, and require several months before the cure is complete. There are, secondly, severe cases. These may present three different types: There is the atrophic or dry type, in which, after an onset similar in nature to that in the slight cases, but much more rapid, the weakness develops into a true paralysis, associated with marked wasting of the muscles and reaction of degeneration, with great diminution of galvanic excitability. Within a week the patient has to go to bed, and then the paralysis soon spreads from the legs to the arms, and may involve the trunk, and even the face. The entire muscular system wastes away, till the patient is a mere skeleton. In addition to the motor symptoms, there is great sensory disturbance. The suffering from pain, paresthesia, and general muscular tenderness, is extreme, and the patient lies totally helpless and unable to tolerate the lightest touch. The skin may be glossy. There is usually some anesthesia, but it is never complete, although it may involve the entire body. The temperature-sense is seldom affected. Pain may be delayed in transmission. There are no gastric symptoms, and no edema. Some cases prove fatal from general exhaustion or intercurrent disease, but the majority recover after a convalescence which lasts a year or more, during which the muscular system is rebuilt.

There is, secondly, the hydropic or wet type. In these heart-failure appears early, and is associated with a marked decrease of arterial tension and much edema of the entire body, effusion into the cavities being added to that beneath the integument.

The swelling of the edematous parts conceals the atrophy which is going on in the muscles, but this is indicated by the paralysis, which is as severe as in the preceding form, and it becomes evident during recovery, when the edema has subsided.

There is, thirdly, the acute, pernicious type. In this all the symptoms of the two former types appear in rapid succession, and, in addition, gastro-intestinal symptoms and a suppression of urine combine to make the condition an alarming one. Effusions into the pleura and pericardium appear early. The pulse becomes small and irregular, and cyanosis indicates the heart-failure which precedes death.

In this form, the disease may run its course in two weeks to a fatal termination. This was the form which chiefly prevailed in Manila, the cases of the atrophic form being the ones which recovered.

The severity differs much in different epidemics, the mortality varying from two per cent. in Japan to sixty per cent. in Manila. It is usually not above three per cent. In all the forms there is some danger of a sudden heart-failure, and this is usually the cause of death.

The morbid anatomy of this disease is, primarily, a multiple peripheral neuritis, with, secondarily, numerous organic changes in various organs, none of which, however, are essential to the disease.

While we cannot join in the wish expressed by an enthusiastic German author, that the disease may soon become a familiar one to those outside of Japan, we cannot pass it by without a brief reference, especially as it resembles in so many of its features, as well as in its pathological basis, the condition which has occupied our attention at present. And it may not be unprofitable to obtain a clinical picture which differs somewhat from that already viewed, in connection with the forms more familiar to us, in order to detect sporadic cases of the disease, if such should appear among us. As to its treatment, it may be mentioned that quinine failed to influence its course, and that heart stimulants to combat the dangerous complications, hypnotics to counteract the pain and insomnia, and general tonic treatment have proved of the greatest service. Change of climate often is attended by recovery. In the stage of recovery, electricity and massage have been employed with advantage.

#### PERSONAL EXPERIENCE IN THE TREATMENT OF CANCER.<sup>1</sup>

BY J. COLLINS WARREN, M.D.,  
Assistant-Professor in Surgery, Harvard University; Surgeon to the Massachusetts General Hospital.

I HAVE chosen this title for my paper this evening, not with the intention of bringing before the Society any new or original mode of dealing with this disease, nor of presenting any carefully-tabulated series of cases, but simply for the purpose of recording a few of the conclusions which I have arrived at, in the hope that they may not be without interest to others.

I regret to say that I have no data which throw any light on the etiology of this disease. It may not be out of place, however, to notice a few facts bearing upon this point which the literature of this subject affords. The influence of locality seems to be not without its effect upon individuals. A notable example of this has been observed in the cobalt mines of Schneeberg, where all the men, who work a certain number of years in the mines, die of lympho-sarcoma of the lungs, but none of the persons employed in the neighborhood are affected with this disease.

It has been said that in tropical climates cancer is much less frequent than in the temperate zone, but I have not had an opportunity of studying any statistics bearing upon this point. It is stated that Dr. Haviland has found from statistics that, while high and dry lands are free from cancer, the courses of large rivers subject to seasonal overflow are hot-beds of cancer, the inference being drawn that the organisms of cancer

thrive only or chiefly in moist districts, or in the tissues of those who reside in moist river districts.<sup>2</sup> So far as I am aware, no such geographical distribution of cancer has been observed in New England.

It would exceed the scope of this paper to endeavor to accumulate evidence upon the origin of cancer from injury or inflammation. Examples of cancer following a continual irritation are sufficiently numerous, as in the lip, to justify the assumption that there may be some relation between the local irritation and the new growth. One of the most malignant forms of cancer of the breast that I have seen, dated its development from a blow. The patient was a healthy and finely-developed Irish servant-girl, under thirty years of age. She received a severe blow from a base-ball, and the inflammation thus produced left a hardness, which did not disappear. So rapid was the growth, that an exploratory incision was needed to confirm the diagnosis of cancer.

A chronic balanitis, with thickening of the prepuce, due to an attempt on the part of a patient to cure a phymosis with a razor, was followed by an epithelial ulcer in the sulcus, below the corona. Excision of the ulcer in this case had not been followed by a return of the disease when the patient was seen a year or two later.

On the other hand, there may be a chronic inflammation of an organ, frequently attacked by cancer, which may continue for a long time without the development of any malignant growth. More than one case of chronic mastitis, with inversion of the nipple and a gland in the axilla, have been sent to me for a diagnosis, which have terminated either in resolution or suppuration. In two cases at present under observation, the inflammation appears to have been caused by the malformation of the nipple which had always existed.

We hear less of the influence of heredity in cancer to-day than did the students of twenty years ago; an example given by Sir James Paget is, however, sufficiently striking to quote: A lady died with cancer of the stomach; one of her daughters died with cancer of the stomach, another with cancer of the breast; of her grandchildren, two died of cancer of the breast, two of cancer of the uterus, one of cancer of the axillary glands, and one of cancer of the rectum. An almost equally marked example is furnished in the case of Miss B., reported below. I have, however, little faith in hereditary tendency, at least, so far as cancer is concerned.

#### CANCER OF THE FACE.

It has been the fashion, particularly in England, to divide cancer of this region into two varieties, namely, cancer of the lip and rodent ulcer.

The great variety of growths placed in the latter category present essential differences, both in development and outward appearance. In many the ulcerating type is absent. They all present a mild type of malignancy, although there may be great variations in this respect within certain limits.

It has been stated that these growths occupy the region of the face situated above the line of the mouth, and this is undoubtedly the case, as a rule. I have, however, at present under treatment a case of epithelioma of the rodent type upon the chin, and have observed them even upon the neck, behind the ear.

<sup>1</sup> Read before the Boston Society for Medical Improvement, January 24, 1887.

<sup>2</sup> H. T. Bullin. International Encyclopedia of Surgery, Vol. IV.

That variety which is usually developed from the epithelial layers of the skin, and frequently accompanied by that condition of the skin of the face and hands known as *keratosis senilis*, is apt to be multiple, and some of these growths may become quite voluminous. Both this variety and that which springs from the sebaceous glands may, at times, assume the ulcer type, though this form does not seem to belong essentially to either.

I am inclined to agree with Mr. Hutchinson's view, that locality has a strong influence upon type. The ulcerating form is most frequently seen near the nose and eyelids; the papillary or tuberosus form more frequently on the cheeks and temples. The crateriform ulcer recently described by this author is an example of an active-cell growth, with consequent central degeneration. It is one of the most exuberant and active types of the so-called rodent ulcer family. A very perfect example of this disease I had the opportunity of watching from its early stages recently. At first a nodular mass was seen on the right temple, about the size of a small nipple. The centre was slightly umbilicated. A sudden increase in the rapidity of growth, with corresponding increase in the size of the central depression, developed its crater-like appearance, and necessitated active surgical interference.

Examples of the multiple growths are not uncommon. Mr. J. B. M., a gentleman sixty odd years of age, has been under my observation for ten years, during which time a very large number of epithelial growths have been removed from the face and hands, some of considerable size. During this period he has also been under Dr. White's care for a very striking form of *keratosis*. One of those curious freaks of which many diseases are capable has occurred within the past year. Last summer he had a small growth removed from the eyebrow. A larger growth of epithelium was beginning to form on one ear, and a fresh outbreak of the disease appeared imminent. A sudden and marked improvement began about three months ago, and his face and hands appear to be entirely free from *keratosis*. He attributes this change to the persistent use of vaseline at night.

I have had but little experience with the use of caustics, as I find little difficulty in persuading patients to resort to more radical measures. Very small growths may be destroyed by an application of nitric acid, or boring with a pencil of nitrate of silver.

When not of minute size the question of deformity becomes the most important one in determining between excision or the curette and cautery. Small epithelial growths or ulcers may be neatly removed by excision. A linear wound, held together by two or three stitches, needs no dressing and unites by first intention. If the sutures are removed early the scar will soon be difficult to find. The cautery will be much more likely to leave a visible scar in the shape of a smooth and white and slightly depressed cicatrix. If, however, the disease is situated in some sharp angle of the face, as in the neighborhood of the nose, it is difficult to be as economical of tissues with the knife as with the cautery, and the use of sutures is liable to bring the edges of the wound together in a way which will produce more deformity than when nature herself is allowed to borrow skin from all directions. A prominent ridge near the nose or eye may be avoided by allowing the wound to heal by granulation.

When larger wounds are necessary, an attempt at healing by first intention will cause some constitutional disturbance which may not be desirable in old and feeble individuals. The cautery leaves an open wound protected by an eschar, and subsequent pain and fever are rarely observed. Ordinarily these wounds need no dressing for the first few days, and when of considerable size may heal by scabbing. Occasionally there may be a secondary hemorrhage, which is usually a slight affair and easily checked, but it is likely to alarm the patient and necessitate an uncomfortable bandage. In extensive disease or irregular-shaped growth of the face, however, it causes far less deformity than the knife. The curette should always be used with the cautery, as the soft superficial masses of epithelium are readily removed in this way; the finger-like projection of epithelium into the subjacent fibrous stroma can be readily attacked by the hot platinum. The curette should never be used alone even in the smallest growths, for there is almost in every case a projecting off-shoot of the disease penetrating the denser tissues which will escape the instrument. The stick of nitrate of silver may be substituted for the cautery in such cases.

A striking instance of the advantages of the cautery (Paquelin) has recently occurred to me. The disease had involved the integuments of one side of the nose and an adjacent portion of the cheek, and had begun to invade the opposite side. One ala was entirely destroyed, and the part above the inner canthus of the eye, a dangerous locality from a prognostic point of view, was on the point of being invaded. A thorough use of Paquelin's cautery, under ether, completely removed the growths at one operation and the nose is now covered with a clean and smooth cicatrix. No pain or constitutional disturbance was experienced at any time by the patient, who was seventy-five years of age. For several days the eschar served as an excellent dressing, and no other was used until later.

Since the introduction of cocaine I have used it in several cases with satisfactory results. An ulcer on the chin, about the size of a half-dollar, was cauterized without pain, although the epithelial masses penetrated quite deeply. No other assistance was given than that of the patient himself, who worked the bulb vigorously while the cautery was applied. It was necessary to use the subcutaneous injection of a few drops of a twenty per cent. solution at several points in the periphery of the ulcer. Alarming symptoms have been reported as following the use of three drops of a solution of this strength under the mucous membrane of the mouth. I have noticed on two occasions in this patient, symptoms of faintness and distress apparently due solely to the cocaine, but these have followed also the injection of a ten per cent. solution in the same individual. The anesthesia has not been complete in this case, except after the use of the twenty per cent. solution. Where there is an ulcerated surface it can be painted over with one of the weaker solutions with good effect. It promises to replace ether in a certain number of cases.

The care of the skin is an important feature of these cases. The epidermis must be kept in a soft and pliable condition, and not allowed to accumulate. Various substances, as salicylic acid or zinc in vaseline as a vehicle, may be applied after washing with appropriate soap. The liability to recurrence varies, of course, with the progress the disease has made, but

some cases recur with obstinacy even when removed at an early stage. An example of this characteristic is shown in the case of Mrs. P., aged about sixty, from whom I removed a nodule on the bridge of the nose, in 1872. A suspicious scab was removed shortly after, but the microscope failed to detect any cancerous cells in it. The disease returned in about eighteen months, and before she could make up her mind to another operation, had involved the integuments of the whole bridge of the nose. It was thoroughly cauterized under ether, but in a year or two it broke out again; treatment was continued until 1883, but as I was unable to promise a radical cure the patient finally abandoned treatment. She is, I think, still living with a well-developed rodent ulcer on this region.

As a contrast to this case, that of Mr. S., eighty-two years of age, may be mentioned. He was operated upon in May, 1882, for an extensive ulcer at the outer canthus of the right eye, involving the conjunctive and some of the tissues of the orbit. Although the sight of the eye has been destroyed there has been no return of the disease. He has consulted me since for several small nodules near the lid of the left eye.

#### CANCER OF THE BREAST.

The favorable results which have attended a more radical operative treatment of this affection have given encouragement to surgeons to hope for cure in many cases which formerly were thought suitable only for palliative measures.

The rule has been laid down by some authors that in all cases there should be a thorough dissection of the axilla, whether glands are felt there or not; and some, notably Dr. S. W. Gross, of Philadelphia, recommend a more extensive removal of the tissues of the breast, leaving often a wound which can only be healed by grafting.

The anticipation of glandular disease of the axilla, seems to me a very important step forward in the surgery of the breast. The lymphatic vessels and glands, which are the routes through which the disease travels, are destroyed, and isolation of the disease is more effectively produced in this way than in any other. Small glands may, moreover, already exist, which cannot be detected by the touch of the finger through the integument. It has been my experience to dissect out the pyramidal mass of fat which fills this region, and to find one or two nodules enclosed in its centre, which could not be felt before the operation.

The ordinary duration of this disease if left untreated is said to vary from six months to three years, taking the average of cases. With this period as a standard it will be seen that life is not prolonged in many cases by the operation. But a careful inquiry into the future history of hospital patients would, I think, bring out replies which would prove encouraging.

The following cases are selected as fair samples of what may be accomplished by the present more radical operation.

*Eighteen months' immunity.* Mrs. B., Amesbury, Mass., about sixty years of age. Disease had existed two months. A hard and voluminous cancer of the breast, with large glands in the axilla, extending as high as the clavicle. The breast was amputated and the axilla carefully dissected out, all glands having

apparently been removed. The case was not promising, and one which in former times I should have declined to operate upon. The operation was performed July 9th, 1885, and Dr. H. G. Leslie writes me at present date that there is no evidence of a return of the disease.

*Nearly two years' immunity.* J. D., about forty-five years of age, was operated upon at the Hospital, March 29th, 1884; she had had a tumor nine months, at the time of the operation it was the size of an orange. The records state that no axillary glands were removed, although the cicatrix was seen to extend two or three inches beyond the edge of the pectoralis major when she was examined on her return to the hospital last week, for the removal of a small nodule in the cicatrix, at the axillary end, about the size of a coat button. No glands are felt in the axilla. The microscopic examination by Dr. Whitney showed the original tumor to be a medullary cancer.

*Two years' immunity.* Miss B., about forty years of age, was operated upon in December, 1884. Had first noticed a tumor in breast the previous winter, but had noticed an eczema of the nipple in 1883. A careful dissection of the axilla was made in this case, although no glands were felt. On opening the mass of fat removed, one small cancerous nodule was found in its centre. Inquiry of her physician, Dr. C. P. Putnam, last December, elicited the fact that no return of the disease had been reported at that date.

An interesting feature of her history was the prevalence of the disease in her family. Her maternal grandmother died of cancer of both breasts at the age of thirty. A maternal aunt died of cancer of the breast. A cousin on mother's side died of cancer of the rectum. Aunt on father's side was operated upon at the Hospital in 1883, for a cancer of the breast.

*Two and a half years' immunity.* Miss J., Haverhill, Mass., was operated upon in June, 1884. The breast was very voluminous and the cancerous nodule was small and situated near the sternal boundary. Nevertheless, the incision was carried into the axilla and a portion of the axillary fat removed. I have seen the patient quite recently; her health is excellent and she is able to attend to all her duties, which are quite onerous.

*Three years' immunity.* Grace M., forty-five years old, was operated upon at the Hospital in July, 1883, for a scirrhus of three years' standing, which had not involved the axilla. The tumor had slowly increased in size during this time and the nipple was extracted. She was seen last Spring and carefully examined, the parts being found in a perfectly healthy condition. Her health is good, and she has been in active service since the operation.

Two other localities which are occasionally the seat of cancer may be briefly mentioned in this paper.

#### CANCER OF THE RECTUM,

would not appear to me to be of so frequent occurrence in this country as in England or the continent of Europe, comparing my own experience with the statistics of foreign writers. The worst form of this disease which I have met with has been in the cases of two young women.

The first case was a woman twenty-three years of age. The symptoms were of one year's standing, when she entered the hospital. The patient suffered

great pain in defecation, but the anus was not involved, the disease being wholly within the rectum, which it nearly filled with a very dense mass of tissue. An incision through the disease and sphincter was performed with but temporary relief, and a few weeks later lumbar colotomy was performed, which gave considerable relief, which continued until her death about nine months later.

The second case was a lady about thirty-five years old, with a voluminous growth springing from the anterior wall of the rectum, and filling out the perineum. The pain in this case seemed to be due largely to the growth of the mass, and was largely in the hip. There was also tenesmus and frequent desire to defecate although no obstruction. An active application of the actual cautery was made, as it was feared that colotomy would not relieve the symptoms in this case. The operation freed her from pain, but she sank and died apparently from no special inflammatory process, about three weeks later.

Attempts at extirpation have been quite unsatisfactory, and I am inclined to advise as little interference with the disease locally as possible, unless it be seen at a very early stage. But such a case has never presented itself to me. Indeed, I have never seen one where it seemed mechanically possible to remove the whole growth.

Colotomy is a palliative operation in certain cases, but not by any means in all; for those near the anus it may relieve the acute local pain; for those higher up it is only indicated in case of marked obstruction which, however, does not always occur.

#### CANCER OF THE OESOPHAGUS.

My experience with dilatation of the stricture produced by the disease in this locality has not been encouraging. The painful nature of the treatment and the rapidity with which obstruction occurs on its discontinuance, make this a method unsatisfactory to both surgeon and patient. On one occasion, an attempt to pass the ivory probang in a very old lady with cancerous stricture, although made with great care and gentleness, was followed by death of the patient three days later. In another case, the persistent and most careful use of the bougie, although it kept the stricture from closing entirely, did not prevent great irritation of the oesophagus from obstruction. Considerable inflammation occurred around the locality of the disease, tracheotomy was performed, and at the autopsy, some weeks later, perforation of the oesophagus was found, with the production of which, of course, I had the privilege of being accredited. In a case which has been under treatment during my present service at the hospital, I have accordingly tried the operation of gastrostomy. Until the termination of the case it will not be possible to express an opinion on its merits and disadvantages. The management of the fistula requires an amount of intelligence which the average hospital cannot always be depended upon to possess.

The use of a flexible tube permanently retained in the oesophagus offers certain advantages over either of the other methods, which would incline me to give it a trial.

In regard to the efficacy of drugs in the treatment of cancer, I have had no positive results.

Arsenic has been tried repeatedly in cases of lympho-sarcoma, without the slightest success. In a

recent case of this disease an exploratory incision was made, and since the wound thus made has healed, the tumor has slightly decreased in size. This result may have been due to severing some of the vascular connections of the tumor. I have used chian turpentine also in several cases, without any effect, in cancer of the breast, of the oesophagus and rectum.

The recent publication by Mr. Clay, of cases of successful treatment of cancer of the lip, tongue and uterus, has again called attention to this drug, and the mode of administering it is accordingly given here. Mr. Clay maintains that physicians are too easily discouraged, and that its administration should be continued through the period of at least three months, in order to obtain favorable results.

The mixture which Mr. Clay recently recommended was the following:

Chian Turpentine	...	...	3iss
Flor. Sulph.	...	...	3i.

Divide into thirty pills.

Magnesia should not be used as an excipient, and they should not be coated.

Two pills should be taken three times a day for three weeks; then three pills three times a day, or twenty-seven grains of chian turpentine daily. They should be taken about one-half hour after eating; after being taken for three months, they should be discontinued for three days in every fortnight. Messrs. Metcalf & Co. write me, "The mixture he had made contained five grains of the chian turpentine and two grains of sulphur to the teaspoonful, made up with mucilage of tragacanth. The pills have been much used, but the mixture being rather unsightly and not agreeable to the palate, has fallen out of use." The "Southall" mixture, which he has recently advised, contains resorcine instead of sulphur, but its composition I have not been able to ascertain. I have myself used the following combination:

R.	Chian Turpentine.	
	Resorcine	.. as 3ii.
	Mucilag. Gum Acae.	.. 3ii.
	Aq. Cinnam.	.. 3i.

Sig. Teaspoonful three times a day.

If carefully prepared it is not a disagreeable mixture, but most patients prefer the pills.

I am one of those who are hopeful that a bacterial study of this affection may further our knowledge of its etiology, and pave the way to a more intelligent treatment. It may be that, like the treatment of traumatic infective diseases, this may be prophylactic rather than curative. But it hardly seems possible that with so rapid advances in surgical knowledge in other directions, we should still continue to remain nearly helpless to aid humanity affected with so terrible a disease.

#### THE SO-CALLED PHYSIOLOGICAL LOSS IN INFANTS.

BY CHARLES W. TOWNSEND, M.D.

It has been found that every infant loses weight during the first few days of life. To what is this loss due? Is it physiological or pathological? Can it be prevented, or, in other words, can this handicap of the infant in the race of life be removed? These are the chief questions that present themselves, and their solution has been aided by studies during my service as house-physician in the Boston Lying-in Hospital,

through the courtesy of the visiting physicians, and by statistics obtained from the records.

In this hospital there are records of the daily weight of each infant from May 1st, 1885. As the birth-weight is taken before the baby is washed and dried, it is evident that a portion of the loss in these, as in probably some other statistics, is accounted for by casix, liquor, mucus, and blood, with which the baby is more or less bedaubed at birth.

To determine this factor, four infants were weighed at birth, and again when washed and dried; in none of these cases was meconium or urine passed before the second weighing. The average loss was an ounce and a half, avoirdupois (47.5 grammes), the least being a little less than an ounce (25 grammes), the greatest about three and a half ounces (100 grammes). Another factor in this decrease of weight is, of course, due to the loss of other extraneous matter present at birth, that is, the meconium and urine; these, in a still-born child, were found to amount to an ounce and a half (45 grammes), but as fully half as much again was lost during delivery, the total amount is probably between two and three ounces. Bouchaud<sup>1</sup> gives the weight of meconium in a still-born child as 60 to 70 grammes. From the so-called physiological loss, then, must be deducted that due to removal of casix, meconium, etc., or three to five ounces, and the remainder will be the true loss of fluids and solids of the body over and above the gain by assimilation of breast-milk.

Leaving out the partly and wholly bottle-fed infants, the premature, and those who died or left the hospital within a few days, and those whose mothers had acute diseases, there were at the Boston Lying-in Hospital, between May 1st, 1885, and July 1st, 1886, 231 infants entirely breast-fed from birth till discharge from the hospital, generally on the fourteenth day; of these, 140 were from primiparous mothers, and 91 from multiparous mothers. It is the custom at the hospital to put the child to the breast generally at the end of from six to twelve hours. The breast is given regularly every two hours, and but once, and in some cases not at all, between 10 p. m., and 6 a. m. The following table is an analysis of these 231 cases:

	Infants of Primiparæ.	Infants of Multiparæ.
Average Loss . . . . .	10.47 oz. (296 gms.)	8.90 oz. (253 gms.)
Day Weight was Less . . . . .	Between 4th and 5th day	4th day.
Per cent. who Reached or Surpassed Birth-Weight on 14th Day . . . . .	66%	63%
Average Gain on 14th Day . . . . .	-0.86 oz.	+0.20 oz.
Average Gain in those who Surpassed Birth-Weight on 14th Day . . . . .	5.74 oz. (163 gms.)	6.86 oz. (172 gms.)
Average Loss on 14th Day in those who Failed to Reach Birth-Weight on that Day . . . . .	7.81 oz. (218 gms.)	7.15 oz. (202 gms.)

Deducting one and a half ounces as the average loss from removal of casix as estimated above, the physiological loss is reduced to 8.97 ounces (247 grammes) in the infants of primiparæ, and 7.40 ounces (205.5 grammes) in those of multiparæ. It is seen by reference to the table that the loss is greater in the former than in the latter class, and that the former began to

gain weight a little later than the latter. The gain on the fourteenth day was, however, practically the same in both, as well as the proportion who equalled or surpassed the birth-weight. The fact that the flow of milk is generally later in primiparæ than in multiparæ, and also the fact that primiparæ are not so skilful in nursing, will explain the difference in the initial losses. That at the end of two weeks, however, this slight difference is done away with is interesting, and corresponds with the general idea that first-born children are, as a rule, as strong and healthy as those coming later.

Bouchaud<sup>2</sup> found that out of 54 cases, five did not lose — three of these being first-born children — and that the average loss in 21 normal infants was 100 grammes for the first two days, after which they gained, reaching the birth-weight on the fifth to the seventh day.

Olier<sup>3</sup> gives a chart of an infant weighing 3,130 grammes at birth, sinking on the second day to 3,000 grammes — "*depression normales*" — which he attributes to loss of meconium, urine, and cutaneous evaporation, and reaching on the third day birth-weight — "*ligne de terre*."

Winckel<sup>4</sup> states the average loss as 284 grammes. Henoch<sup>5</sup> gives 200 grammes as the loss during the first three or four days. According to Hoffman, quoted by Eretzky,<sup>6</sup> the return to birth-weight is on the fifth to the sixth day; and according to Bouchut, on the seventh day.

Schütz<sup>7</sup> finds that the average loss of 27 males for two days was 188 grammes, and for 36 females 170 grammes, and that children of multiparæ lose less, and more quickly return to birth-weight than do the children of primiparæ.

Russow<sup>8</sup> states the loss to go on for three days, and the original weight regained on the tenth day, and thinks that a loss always occurs. According to Siebold,<sup>9</sup> quoted by the same author, the loss is 140 to 280 grammes; and according to Haake,<sup>10</sup> the loss in the first twenty-four hours is one-twenty-fourth of the original weight.

Gregory<sup>11</sup> found that infants invariably lose; that of 45 breast-fed infants, 88% began to gain on the second or third day, and 12% after the third day, and that the loss in these two days averaged 203 grammes; that boys began to gain sooner than girls, and that a nourishing diet in the mother shortened the period of the loss. The average infant reached its birth-weight on the seventh or eighth day.

This loss is due, first, to the fact that for the first three or four days, milk is not secreted in sufficient quantity, or of proper quality, to nourish the child; and secondly, to the fact that the infant is not urged by nature to obtain more than a small quantity of this food, and, if not disturbed, spends most of the time in sleeping. In fact, it seems to me that this physiological loss must be greater in cases outside of the hospital, where the infant is not so systematically forced to take the breast, and actually shaken to keep it awake long enough to nurse.

The colostrum, which serves a useful purpose at first as a gentle laxative — a fact denied by Bouchaud<sup>12</sup> — becomes detrimental if it continues in the milk beyond the normal time. To determine this fact in relation to the physiological loss, the milk of 20 women was examined under the microscope daily, or every other day for a week or more, and it was found that the colostrum-corpuscles disappeared, as a rule, on the fifth or sixth day. In one case, a multipara, in whose milk no colostrum was found on the third day, the infant's loss was only eight ounces. In another multiparous case, the colostrum was present till the ninth day, and the infant's loss was sixteen ounces. In the milk of a primipara, a good many colostrum-corpuscles could still be found on the thirteenth day; and the baby, who was entirely breast-fed, lost fourteen ounces. The mother appeared healthy, and had a good supply of breast-milk.

The average physiological loss in five children of multiparae, where the colostrum-corpuscles were absent from the milk by the fifth or sixth days, was ten ounces. These cases are, of course, too few to be of much value, but are, at least, interesting and suggestive.

J. Lewis Smith<sup>13</sup> speaks of an infant six weeks old, who, after the first week, had never thriven, had vomited frequently, and was much emaciated. The mother's milk, which was apparently suitable in quality and quantity, showed, under the microscope, colostrum-corpuscles. A change to a wet-nurse was followed by rapid recovery.

That this initial loss always occurs with the rarest exceptions, notwithstanding the health and vigor of both mother and child, shows that it is physiological at least in the present state of civilization. Whether it occurs among savages I do not know, but the observations of Kehrer<sup>14</sup> on the lower animals are extremely interesting. He weighed once or twice daily, from birth, some 10 puppies, 28 kittens, and 17 rabbits. All of these gained from the first with two exceptions, one, a litter of four puppies whose mother was poorly nourished owing to partial starvation before delivery, and secondly a litter of six rabbits, whose mother took but little interest in them. How often do these two causes operate in the human species? In these cases there occurred a slight initial loss which was certainly not physiological. Kehrer thinks that the loss in the human young is due first to the tardy secretion of milk in their mothers, and this in turn is dependent on the slight amount of nourishment the mothers receive before and during the lying-in period. The lower animals feed as usual before labor, and immediately after it develop a lively appetite, and the milk flow is plentiful from the first. A second cause lies, he thinks, in the condition of the new-born itself, helpless, unable to move from place to place and often unable to nurse properly for three or four days, while the lower animals immediately after birth, often even when attached to the navel string suck vigorously. He, therefore, urges that the infant should be placed to the breast as soon as possible, and that an early and copious secretion of milk be obtained by a nourishing diet for the mother previous to and during the lying-in state.

Is it worth while to try to improve on nature, and, by a partial artificial feeding during the first few days

of life, prevent if possible this loss? This is what is attempted by the sugar teats, the milk and water and the pap with which the infants of the ignorant classes are often stuffed, and generally with disastrous results.

To answer this question the effect on the initial loss was observed when the infant was given additional food, which was done only in children of primiparae. In thirteen infants half an ounce of milk and an ounce of water were given four times daily for the first five or six days in addition to the regular nursing. In ten cases half a drachm of cane sugar in an ounce of water was given in a similar way. In fifteen cases half a drachm of a granulated extract of malt in an ounce of water was given; and in five other cases the infant for the first three to five days was put to nurse at the breast of a woman whose milk-flow was already established, alternately with the breast of its mother, the nursings coming every two hours. The following table shows the results obtained:

	Breast and milk.	Breast and sugar and malt.	Breast and malt.	Mother's breast and another's.	Average 43 cases.
Average Loss.	9.38 oz. (265 grms.)	16.79 oz. (507 grms.)	8.80 oz. (250 grms.)	7.40 oz. (209 grms.)	9.25 oz. (262 grms.)
Day Weight was Least.	5th day.	4 to 5	3d to 4th.	3d to 4th.	4th day.
Per cent. who reached or surpassed birth-weight on 14th day.	83	80	64	80	77 %
Average gain on 14th day.	1.45 oz.	2.66 oz.	0.92 oz.	1.20 oz.	1.51 oz. (42 grms.)

On comparison with the previous table of entirely breast-fed infants, it is seen that there is a slight reduction in the initial loss, most marked in infants fed also from another breast, and a slight increase in the gain over the birth-weight on the fourteenth day, greatest in those fed additionally with sugar, where, curiously enough, the loss is also greatest. The infants also began to gain sooner, and a greater proportion reached or surpassed the birth-weight on the fourteenth day.

The practical objections, however, to this artificial feeding more than counterbalance, it seems to me, the slight benefits to be derived, and unless the greatest care is used, such as can be obtained from trained nurses in a hospital, the results would probably be unfavorable — such results as are seen in the lower class already referred to. The objections, — besides the great one of its being unnatural, — are that in a considerable proportion of cases the presence of artificial food causes vomiting, and in a smaller number diarrhoea, thus at the very start of life interfering with that most important function of digestion and assimilation. Another objection is that infants take the additional food either with great difficulty, or more often so readily that the breast is afterwards refused. In fact after once giving them a taste of artificial food obtained so easily from a nursing bottle, it often requires the greatest patience and persistence to induce them to nurse their mothers. Many mothers under these circumstances would prefer to put them entirely on the bottle and let their milk dry up rather than continue the struggle, or, what is more probable, the milk would dry up notwithstanding their efforts, owing

<sup>12</sup> Loc. cit.

<sup>13</sup> "Diseases of Children," 5th Ed., p. 36.

<sup>14</sup> F. A. Kehrer. Archiv. für Gynäk., 1. 194.

to the refusal on the part of the infant to take the breast.

The objection to feeding from another's breast in addition to the mother's would simply be its impracticability. The fact that it is impossible to prevent the loss even by this method of a plentiful supply of milk, owing to the difficulty in making the baby nurse sufficiently, shows apparently the normal character of this loss.

Bouchard<sup>15</sup> says that infants placed at once on the breast of another in whom the milk-flow is established lose but little or no weight. Schutz<sup>16</sup> and Krüger quoted by Russow,<sup>17</sup> find that infants under these conditions begin to gain quicker.

Another practical point in relation to the initial loss is the matter of early or late ligation of the umbilical cord. According to Zweifel<sup>18</sup> late ligation of the cord by allowing more blood to enter the infant's circulation than in early ligation, renders the infant more vigorous and diminishes the physiological loss. By weighing the blood remaining in the placenta, he estimates that the child receives 190 grammes more blood if the cord is not cut till the placenta is expelled by Credé's method. In eleven infants thus treated he found the average physiological loss to be 156.7 grammes, while in twenty-five where the cord was cut at once, the average loss was 211. grammes.

Meyer<sup>19</sup> thinks that these results are impossible as 100 grammes is equal to one-third of the whole quantity of blood in an average infant weighing 3,300 grammes at birth, and finds that the average gain by waiting till the expulsion of the placenta is only sixteen grammes. Budin<sup>20</sup> and Schücking<sup>21</sup> found a gain of two or three ounces by waiting till the cessation of the placental circulation before tying the cord. I found that the average loss in ten infants,—including two infants of multipare and five additionally-fed infants, whose cords were cut at once on account of asphyxia, so that hot and cold water plunges, etc., might be used, was 13.2 ounces. In five cases not asphyxiated, three infants of primipare and two of multipare, where the cords were cut at once the average loss was 10.8 ounces. In all the other cases it was the custom at the hospital to wait till the cord had ceased or nearly ceased pulsating, before it was tied, but in the cases tabulated always before the expulsion of the placenta. By comparison with the first table it will be seen that in these cases early ligation has little or no effect on the initial loss of weight as compared with late ligation, except in those cases where asphyxia was a factor: here the loss is somewhat larger.

By way of summary it may be said:

*First.* That in the human infant a loss of weight occurs as a rule during the first few days of life, and is therefore physiological in the present state of civilization, although it does not occur in the lower animals.

*Second.* That this loss is somewhat greater in infants of primiparous than of multiparous mothers.

*Third.* That it is due first to the tardy secretion of milk, and in some cases is increased by the abnormally long continuance of colostrum in the milk,

and secondly to the feeble condition of the infant at birth.

*Fourth.* That the use of additional artificial food or another woman's milk diminishes but does not do away with this loss, and that the practice is for many reasons objectionable.

## Hospital Practice.

### BOSTON CITY HOSPITAL.

#### A CASE OF RECURRING INTESTINAL OBSTRUCTION; RIGHT LUMBAR COLOTOMY; RECOVERY.

SERVICE OF E. H. BRADFORD, M.D.  
REPORTED BY OLIVER H. HOWE, M.D., formerly House-Surgeon.

KATE MCD, thirty-five years of age, single, and a domestic, entered the Hospital (service of Dr. Gay), March 12th. She said that about five weeks previous she had no movement of the bowels for a week, and had more or less vomiting during that time. This attack was followed, a few days later, by a similar one of the same duration. Following this she felt perfectly well, her bowels moving at least every second day (but generally after medicine), the dejections being small in amount.

Eight days ago she had a scanty movement, since which time she has had no movement, although she has taken large doses of various cathartics. She left off work a week ago, and for the last four days has had frequent vomiting, with constant pain and rolling of her bowels. Says she has been unable to sleep, and has lost considerable flesh.

Said she had always had good health, and that previous to the attack first mentioned her bowels had always been regular. Her father died of cancer of the stomach; otherwise her family history is negative.

Patient is somewhat thin and spare, but does not seem to be much emaciated. Countenance has a rather anxious expression; tongue shows a light, whitish coat. Abdomen is moderately and uniformly distended; tympanitic throughout. Pain mostly at left of umbilicus. Some tenderness in epigastrium and left iliac fossa; gurgling in the latter locality. No tumor to be felt. No hernia nor history of any. Rectum empty, and shows no stricture. Temperature 99.6°, pulse 72.

She was given milk and lime-water to drink, and laudanum fomentations were applied to the abdomen. The next day the distension was slightly less, and she was given calomel, gr.  $\frac{1}{4}$ , and bismuth, grs. v, every four hours; also nutritive enemata.

The following day (two days after entrance) she had a small dejection. The next day two good dejections, followed by much diminution of the abdominal distension and relief of all her symptoms. After remaining a week longer, and having daily movements with the aid of occasional laxatives, she went home.

Six days later she returned to the Hospital, having had no movement during that time. The attack was precisely similar to the one preceding, and was relieved in the Hospital by the same means in the same time. The matters vomited consisted, as before, entirely of food, and were stercoraceous. Patient remained in Hospital two weeks, during part of which time cathartics had to be used.

Ten days later she reentered the Hospital (this time

<sup>15</sup> Loc. cit.

<sup>17</sup> Loc. cit.

<sup>18</sup> Centraltbl. f. Gynæk., No. 1, 1878.

<sup>19</sup> Centraltbl. f. Gynæk., No. 10, 1872.

<sup>20</sup> Publie du Progrès Medical, 1876.

<sup>21</sup> Berlin Klin. Woch. 1 and 2, 1877.

on the medical side, in the service of Dr. Mason) having had no movement for eleven days. Symptoms the same as before, but more intense. She was given various cathartics and high enemata. The latter brought away only a few granules of fecal matter. A rectal tube was passed up a distance of eighteen inches, without meeting any obstruction or bringing away anything. After having been in the Hospital two weeks, and having had no movement for twenty-five days, the patient was transferred to the surgical side (service of Dr. Bradford), to receive more radical treatment, if necessary. At this time the abdomen was tightly distended and tympanitic, no tumor being felt at any point, even on deep pressure. Four days later a scanty movement of the bowels occurred. The pain and distress of the patient being constantly greater, the emaciation being more marked, and cathartics having been used in good variety and combination, with the exception of one scanty movement, the obstruction now having lasted thirty days, operative measures were determined upon.

Dr. Bradford decided to do right lumbar colotomy. He was led to this decision by the belief that laparotomy would be fatal in the present condition of the patient, especially as the bowels were so distended. An objection to the operation of colotomy was that, the seat of the obstruction being unknown, it might be above the part of the colon selected, so that the operation might fail to give relief. Had this event been encountered, it was Dr. Bradford's purpose, on perceiving that the colon was not distended, to go to one side of the latter, and, entering the peritoneal cavity, to pull out and open the first distended bowel that could be found.

The patient being etherized, an incision five inches long, and parallel to the crest of the ilium, was made in the right lumbar region. This was carried down through the muscles, until the distended ascending colon was found. The latter was sewed to the edges of the wound, and then carefully opened. Gas and feces freely escaped, and the distension of the abdomen was soon much diminished.

The ends of the wound were sewed up, and a large oakum dressing applied. The next day the abdominal distension was wholly gone, and the symptoms entirely relieved. No tumor could be felt in the abdomen, even on deep pressure. General condition of patient rapidly improved. The liquid fecal discharge was profuse for a day or two, but later became somewhat periodical. The dressing was reduced to a small pad over the opening, which patient cared for herself. She was in no way offensive to those about her, except occasionally from wind. She left the Hospital two months later, the extremity of the incision having entirely healed, leaving a round opening, which just admitted the finger. Reported a month later, and was in the same condition, with no further trouble.

Patient reported again four months later (seven months after the operation). She was found to have improved greatly in strength and general appearance, and to have gained in weight. The opening made by the operation had contracted in size, so as to barely admit the little finger, which it tightly grasps with a somewhat sphincter-like action. Prolapse of half an inch of the bowel through the opening occurs at times. She wears over the opening three or four thicknesses of cotton cloth, kept on by a swathe.

The cloths require changing from one to five times

a day. She lives largely upon milk and white bread, in order to keep the feces from being too liquid. The feces have never been "formed." She says the odor and flatus are somewhat troublesome, and that she cannot go to church or to other gatherings of people. She has been employed as a domestic, and thinks she has not been especially offensive to others while at work in that capacity. Three weeks ago she had a small movement *per rectum*. Palpitation of the abdomen shows the presence of no tumor or abnormal condition. No further light is gained about the source of the obstruction, and it must remain for the present a mystery.

## Reports of Societies.

### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. BUCKINGHAM, M.D., SECRETARY.

JANUARY 24, 1887. The President, Dr. F. W. DRAPER, in the chair.

#### REMOVAL OF UTERUS, OVARIES, AND FALLOPIAN TUBES FOR FIBROID.

DR. JOHN HOMANS showed a uterine fibro-myoma which with its ovaries and Fallopian tubes, had been removed by laparotomy two days before, the whole mass weighing twenty pounds. The patient was a single woman, of forty-five, whose life had been made a burden by this growth. So far the pulse has not been above 80, nor the temperature above 99.4°. The stump was treated externally, that having proved the better way in the personal experience of Dr. Homans. It is an operation accompanied by some shock, and is not, in his opinion, an operation to be undertaken lightly, and this is seen from the fact that he has operated five or six times in the last year, having seen perhaps, from two to four cases almost every week. The speaker referred to the cases reported to be cured by Apotoli by means of electrolysis, which acts, as he is informed by Dr. Amory, by causing exosmosis.

DR. J. C. REYNOLDS said that he had seen electrolysis used by Dr. Cutter and that he had received an account of the practical disappearance of the tumor.

DR. J. C. WARREN read a paper entitled,

#### PERSONAL EXPERIENCE IN THE TREATMENT OF CANCER.<sup>1</sup>

DR. D. W. CHEEVER said that he had been asked to open the discussion on this subject, and in doing so wished to express the pleasure and interest with which he had listened to Dr. Warren's paper. The conclusions arrived at therein did not differ, as he recalled them, from those given in the writings of the late Dr. J. Mason Warren. He would like to add some cases from his own experience.

Cancer was said to be more frequent now in this section than formerly, and he was inclined to think this was true.

The natural history or duration of cancer varied with the age of the patient—in youth being much more rapid than in old age. It varied also greatly according to the organ or locality involved. Its rapidity of growth and the duration of life were approximately in the following order: Tongue and

<sup>1</sup> See page 154 of this number of the Journal.

throat, four months to one year; antrum, one year to eighteen months; testis and penis, about the same; rectum, two years to two and one-half years; uterus, a little longer; breast, two and one-half to four years; skin, indefinite, often many years.

The natural duration of cancer of the breast, untreated, varied in the estimate of modern authors as follows: the elder Doctor Gross, two and a half years; Bryant, two to three years; Agnew, about the same; Paget, four years.

Dr. Cheever was inclined to accept the longer estimate as more nearly correct, except in cancer coming on during lactation, where he had seen two cases terminate in less than one year. He would mention a case of untreated cancer of the breast, which died in the City Hospital, lasting quite four years, and entering the hospital after three years and eight months, in a stage of advanced ulceration.

As to the average period of exemption after excision of the breast, Gross puts it at one year; Erichsen, at one year and a half. Dr. Cheever mentioned two cases of his own: in one there was an exemption of four years; and in one, an exemption of five years. Much longer periods were on record.

In favor of an operation it was proper to say that the mortality from excision of the breast was extremely low; not over six per cent; that anesthesia had robbed the operation of its terrors, and that anti-septic treatment had reduced suffering and hastened convalescence.

Relief and prolongation of life were sometimes the result of operation under the most desperate circumstances. Last June he was called in consultation to see Mrs. G., who had concealed a cancer of the breast from her family until it had burst and ulcerated, and was thoroughly septic and decomposed. Her temperature was high; constitutional irritation great, and every circumstance unfavorable. She assented to a complete and rapid excision, as giving a small chance of life. The tumor was enormous and the wound left by incision very large. She made a prompt and speedy recovery, and called at his office at Christmas, active and well.

On the other hand, it was sometimes impossible to estimate the depth of the cancerous cachexia by the external appearance of the patient. Mrs. T. was operated on in October last. She appeared vigorous—the breast had not ulcerated—the scirrhus was somewhat adherent to the pectoralis muscle, but no indurated glands could be felt. The operation was easy. Some glands were found affected in the axilla, and this cavity was dissected out. For a week she did well, then she had pleuritic effusion under the wound. The fluid was aspirated twice without relief, it was sanious. She sank with pleuro-pneumonia and died in forty-eight hours. The cause of death was then supposed to be septic absorption, but an autopsy revealed cancer of the pleura and of the liver.

Excision of cancer of the breast relieves disgusting effluvia, and thus adds to the comfort of the patient. It was a mistake to suppose that it relieved suffering, after recurrence. Death was as painful and suffering as prolonged after recurrence, as in cases left to run their natural course.

Miss R. gained her livelihood by type-writing. She came to Doctor Cheever with a small, deep, adherent carcinoma of the breast. It was painless and did not interfere with the free use of her arm and hand. He

advised against operation, because she was dependent on her hands, and he feared that the disease was irradicable and that the scar of an operation in a thin subject, and with the pectoral involved, would prevent subsequent free use of the arm. Four months later it ulcerated a little and alarmed her by trivial hemorrhages. She desired operation. Excision of the breast was done, convalescence was slow, adhesion took place. The arm was nearly useless. Cancerous asthma supervened, and she lingered eight months in great misery, and died sitting up in the distressed and bowed attitude of the sufferer from advanced cardiac disease. She did not leave her chair or lie down for eight weeks before death.

Was any other mode of removal better than the knife? Caustics were no safeguard against recurrence.

Some years since a woman entered his hospital service in the following condition:

The mamma was gone; the pectoralis major and minor muscles; the serratus; the intercostals and two ribs; a third rib necrosed, detached at its external end, and flapping like a loose hoop; the costal pleura was exposed over a large surface, and granulating. This extraordinary destruction had been accomplished by a paste applied to a cancer of the breast by a female charlatan.

The woman remained in the hospital all winter. Aided by grafting, cicatrization was nearly completed, but before she left the hospital, hard and tuberos masses of cancer appeared in the neck and arm.

In epithelioma of the skin of the face and neck in the aged, Dr. Cheever used caustics with much benefit. He had preferred the chloride of zinc (Canquary's paste), which was nearly painless. He thought the use of Paquelin's cautery would prove extremely valuable, as in Dr. Warren's cases. He had recently noticed the remarkable arrest of growth in ulcerating epithelioma produced by an intercurrent attack of facial erysipelas. The elder Dr. J. Collins Warren had mentioned this phenomenon.

The arguments in favor of operating on cancer of the breast were:

- (1) The moral effect on the patient, which was very great.
- (2) Cleanliness.
- (3) A period of exemption, and a probable prolongation of life.

Dr. Cheever had been quite positively convinced of the beneficial effects of some other local remedies, such as submucous injection of a saturated solution of citric acid in the cylindrical epithelioma of the rectum. Glacial acetic acid made a slough. Citric acid tanned and shrunk the parts. Some growths of doubtful character in the breast had disappeared, under his observation, under large doses of bromide of potash, given by the mouth. And some in the parotid gland under the use of the bichloride of mercury taken by the mouth, in minute doses for many months. Chian turpentine, he thought, relieved the pain of rectal cancer sometimes, but not always. Cocaine injected subcutaneously, had produced cardiac distress and faintness in two cases.

Dr. Cheever wished, in closing, to say a word in favor of the repeated removals of sarcoma, which was a locally recurrent disease. Life can be much lengthened by operating over and over again, where the growth is accessible. The late Dr. March, of

Albany, operated on a sarcoma of the neck in an elderly lady. It recurred, and Dr. Cheever removed it five times. These six operations covered ten years. The first was done at the age of sixty-eight, and the last at the age of seventy-eight years. The patient finally died of pneumonia, one year after the sixth operation.

DR. J. C. WHITE said that his experience with carcinoma had been mainly with its superficial manifestations. He sees many cases of epithelioma in an early stage; and merely wishes to call attention to the importance of recognizing the disease while it is comparatively simple and harmless. In *hepatosis senilis* the early changes consist in a heaping up of cells of the upper layer, subsequently the lower cells became heaped up and undergo changes. By the early use of soaps, salicylic acid, cosmoline or vaseline cases can often be restored to their normal condition, that is, cured. Scaly masses, with change of color, upon the back of the hand, the face or the neck, can often be cured without the use of curette or knife. When sebaceous warts tend to be soft, scales form in masses, soften and fall, leaving a scab. Such warts may be treated with a pointed stick dipped in concentrated nitric acid. The stick can be pushed into all the recesses of the skin and the acid penetrates farther than the stick. Unless free bleeding occurs to dilute the acid, there will be probably a superficial scar. If driven deeper, there may be marked destruction of the skin. He never tried this method in cases fit for excision, but in the beginning, nine out of ten cases of epithelioma may be cured by it.

A mistaken diagnosis is often made because of age. True epithelioma may be found between twenty and thirty, or even fifteen and twenty, or even at twelve years.

DR. JOHN HOMANS expressed his opinion that it is wise in removing sarcoma or cancer, to start with the resolution to remove it as often as it returns, for as long a time as possible. In one case a sarcoma had returned before the patient had recovered from his first operations. He removed it again, and there has been no other return for nineteen years. He mentioned a case of a cancerous tight annular stricture of the rectum, in which the bowels had not acted for six weeks. The patient was too tender to be removed. He performed colotomy and afterwards the patient was able to be about shopping. Finally, a rubber tube dropped into the wound. He was not allowed to remove it, and death resulted.

Dr. Homans also spoke of the value of statistics. We do not know as much as we should of the after history of hospital cases. When younger, and with more time at his disposal, he had offered to follow up these cases of one of our hospitals by correspondence with physicians and patients, but was not encouraged to do so. He thought however it would be valuable work, and not merely so with cancer. There was room for it in the study of tracheotomy, for instance.

DR. M. H. RICHARDSON said that he thought the method of inquiry proposed by Dr. Homans would be valuable; but to be so, it should be limited to cases in which the diagnosis is certain, in which the microscope has been used.

He said that he has yet to see the case of cancer of the breast, in which the axillary glands cannot be detected. Of course, if they are thoroughly dissected away, there can be no return in these glands.

## MEDICAL SOCIETY OF THE STATE OF NEW YORK.<sup>1</sup>

EIGHTY-FIRST ANNUAL MEETING, HELD AT ALBANY, FEB. 1ST, 2D, AND 3D, 1887.

### SECOND DAY — AFTERNOON SESSION.

A resolution was passed, making the term of delegates to the Society three instead of four years, and enabling them to become permanent members after two successive years' attendance on the Society, instead of three. The object of the resolution was to increase the membership. The question of receiving delegates from certain other organizations will be voted upon next year.

DR. E. T. BRUSH, of Mt. Vernon, read a paper on the

#### MAMMARY GLAND.

After a humorous introduction in which he quoted instances of the secretion of milk in the mammary glands of the unimpregnated females as well as in the male, and deplored the fact that the product of the human female mammary gland was threatened with competition not only by the baby-fool war, but also by the male wet-nurses of the future, Dr. Brush gave his own experience with cases of mammary abscesses. He pointed out that, as there is an excessive activity in the gland during the puerperal state, disturbances in other parts of the economy produce pathological changes in it; that a malarial chill, rheumatic seizure or the like, is often at the bottom of the trouble, and that by treating these constitutional symptoms the local manifestation could be aborted, and that this, indeed, was the rationale of the exhibition of quinine or salicylic acid in cases of abscess. For sore nipples he proposed a new acid, according to his statement, an affectual method of preventing or remedying this troublesome annoyance; for painful abscesses he recommended ice-bags, and, if necessary, strapping and bandaging; and in galactorrhoea, ergot, quinine, and iodide of potassium. For emptying the breast he preferred hot bottles as more efficient and gentler than breast-pumps, many of which he described as simply barbarous. He alluded to the fact that in the human female, pus never exudes from the nipple, while in the bovine female it always exudes from the breast.

#### REPORT OF THE COMMITTEE ON PRIZE ESSAYS.

The Merritt H. Cash prize was awarded to Dr. A. N. Bell, of Brooklyn. The title of his essay was, "The Physiological Conditions and Sanitary Requirements of School-life and School-houses." Eight essays had been received. Later it was voted to authorize the secretary to send one thousand or fifteen hundred copies of this essay to the municipal and school authorities throughout the State.

OBSERVATIONS ON REFLEX NERVOUS DISTURBANCES, was the title of a paper by Dr. W. E. FORD, in which he held that many of the conditions commonly ascribed to reflex causes were due to actual lesion of the spinal cord. Operative procedure for the relief of reflex disorder often failed of its object.

DR. ROSWELL PARK read a paper on

#### THE SURGERY OF THE LUNGS,

Treating of the subject under the following heads:

<sup>1</sup> Concluded from page 159.

(1) Historical; (2) Pneumotomy, — indications for, — operations — results; (3) Pneumectomy — experimental and clinical — indications for — the operation described; (4) Thoracoplasty — Estlander's operation and its modifications — general principles upon which it is based — reports of cases.

Pneumotomy was indicated in bronchial abscess, tubercular abscess, gangrene of the lungs, hydatid cysts, and foreign bodies. The mortality-rate had been a little over thirty-two per cent. The clinical reports from pneumectomy were of a limited number. It was resorted to in hemorrhage from the lung, wounds of the lung, hernia of the lung, neoplasms, and tubercular disease of one lobe. The future of this operation for tubercular disease at the apex was uncertain, but he hoped it would prove useful. The chief indication for thoracoplasty was empyema. — The paper was discussed by Dr. Weir.

#### THE RELATION OF LARYNGEAL TO PULMONARY PHTHISIS, AND THE IMPORTANCE OF LOCAL TREATMENT.

DR. C. C. RICE, of New York, read the paper, and said that about one-fourth of all deaths reported were from pulmonary phthisis; in about one-third of this number there was laryngeal phthisis. Yet it was evident that much fewer than this number received suitable local treatment. He asked, is laryngeal phthisis always tubercular? Is the deposit of tubercle always the primary lesion, or is it deposited often secondarily to catarrhal laryngitis of simple character, aggravated by the bad condition of the patient, and going on to the stage of ulceration? When tubercle becomes deposited, does it render the condition entirely different from the ordinary catarrhal process?

That tubercular laryngitis is not an inappropriate name, has been shown. While tubercular infiltration is known to be frequent among cases of laryngeal phthisis, yet its presence does not imply a disease which runs a typical course, or one in which the prognosis is always bad. Many of the cases of laryngeal disease, apparently laryngeal phthisis, connected with pulmonary phthisis, showed microscopically only the signs of simple catarrhal laryngitis. In some cases the diagnosis of laryngeal phthisis of tubercular character was evident, when there were no indications of phthisis in the lungs.

The function of the larynx was often a cause of its inflammation; from this he suggested that in the treatment there be complete rest of the larynx so far as use of the voice was concerned. Inasmuch as laryngeal phthisis, in his opinion, is not always laryngeal tuberculosis, he regarded the name tubercular laryngitis as unfortunate. The author then spoke of the importance of local treatment, particularly before the stage of ulceration, and also for the relief of symptoms after the stage of ulceration.

DR. FRANCKE H. BOSWORTH, of New York, referred to the fact that Mackenzie had been quoted, in contradiction to his former assertions, to the effect that laryngeal phthisis is not always laryngeal tuberculosis. Absence of the bacillus tuberculosis had been shown in the early stage of some cases of laryngeal phthisis; and the importance of this point could not be overestimated, as it was a generally accepted fact that tubercular laryngitis was usually fatal.

DR. O. B. DOUGLASS had in dispensary practice obtained some almost miraculous results in laryngeal

phthisis from the use of terpin, in about six-drop doses three times a day.

DR. A. WALTER SUITER read a paper on  
SOME POINTS OF MEDICO-LEGAL INTEREST IN THE  
SCIENTIFIC INVESTIGATION OF THE CASE OF THE  
PEOPLE *versus* ROXALANA DRUSE.

#### INTUBATION OF THE LARYNX.

DR. E. L. PARTRIDGE, of New York, read a paper in which he continued the discussion on Dr. O'Dwyer's method of intubation of the larynx, referring in detail to the possible difficulties arising in its performance, etc. The paper was also an argument in favor of the employment of the method which did not preclude the use of tracheotomy, should intubation fail.

DR. A. JACOBI said that when Bouche, of Paris, proposed intubation of the larynx, many years ago, he, Dr. Jacobi, lifted his voice on this side of the water, as did Trousseau and others in Europe, against the suggestion as being practically absurd. When about two years ago he heard of O'Dwyer's method, he also expressed publicly his opinion that it would fail. He had now, however, become convinced of the utility of O'Dwyer's system of intubation of the larynx, and he did not doubt but what the inventor's name would go down to posterity.

#### SOME CONSIDERATIONS CONCERNING CANCER OF THE UTERUS, ESPECIALLY CONCERNING PALLIATIVE TREATMENT IN THE LATTER STAGES.

DR. A. F. CURRIER, of New York, in a paper with this title reviewed the views held by eminent pathologists regarding the anatomy of cancer, also regarding radical operations for cancer of the uterus, and then spoke of the treatment commonly adopted in the cancer hospital at New York, which consisted in removing, by cutting instruments, such portion of diseased tissue at the neck as it was practical to remove in that manner, then the employment of the cautery, the application of a caustic of chloride of zinc, the removal of the slough, the dietary and hygiene of the patient. Life might thus be prolonged, and particularly rendered as comfortable as possible.

#### THE DUTY OF THE MEDICAL PROFESSION IN PROMOTING CREMATION.

SIR T. SPENCER WELLS, honorary member, sent the paper, which was read by Dr. A. Jacobi, who followed with some remarks. The author of the paper referred to the teachings and example of the distinguished Gross, and thought American physicians should not allow the lesson to go unheeded. He also sent two addresses on the subject of cremation, which he had read at meetings in England. Dr. Jacobi, in some written remarks, presented what had been said on the other side of the subject by different writers. As offsets to the assertion by those who insisted upon the necessity of cremation for sanitary purposes, it had been questioned as to what extent contamination of waters, etc., had taken place from burial grounds, and to what extent disease had been spread during burial ceremonies. Further, whether such contamination and such spread of disease could not be entirely prevented by change of the burial system. It was also questioned whether cremation would do away with these dangers to the public health. Aside from the question of sanitation, arose the question of

destroying the evidences of possible criminality by cremation.

#### PRACTICAL OBSERVATIONS ON ABDOMINAL SURGERY.

DR. W. GILL WYLIE, of New York, said his paper would consist of the report of 124 laparotomies, the use of hot water, and treatment of septic peritonitis and intestinal obstruction after laparotomy by the use of purgatives, etc. The cases of laparotomy included all that he had operated upon since November, 1882; 47 of the cases were operated upon in 1885, and 55 in 1886. Of the entire number, twelve died. If three deaths from suprapubic hysterectomy were excluded, the death-rate would be about seven per cent. Of 74 cases operated upon for removal of the uterine appendages, nearly 50 per cent. were cases of genuine pyosalpinx. Of the last 37 of the 74 cases only one had died. He employed hot water in the peritoneal cavity during and just after the operation, to prevent shock and to stop oozing of blood. Tympanites and vomiting supposed to be due to septic peritonitis after laparotomy, were best overcome by enemata, and if these failed then by purgatives. The bowels should be kept free, not constipated.

The President's Annual Address, entitled,

#### THE ACHIEVEMENTS IN SCIENCE AND LETTERS OF MEN WHO HAVE BEEN CONNECTED WITH THE MEDICAL PROFESSION,

was read in the assembly rooms of the Capitol.

#### THIRD DAY. — MORNING SESSION.

##### SPREAD OF CONTAGIOUS OPHTHALMIA.

DR. LUCIEN HOWE, of Buffalo, offered the following resolution, which was adopted:

*Whereas*, the census reports and other reliable statistics show an alarming increase of blindness in the United States, entirely out of proportion to the increase of population; and, whereas, examination indicates that the cause of this is contagious ophthalmia, therefore, be it resolved that a committee of three be appointed to investigate this class of diseases, and recommend means for its remedy. The President of the United States and Officers of the State Medical Society were called upon to render assistance in this work.

##### SYPHILIS OCCURRING IN CONNECTION WITH OTHER DISEASES OF THE SKIN.

DR. L. D. BULKLEY, of New York, thought it probable that syphilitic eruptions had occurred in connection with nearly every other skin disease, but he had seen it in connection with the following among others, and had found the diagnosis more or less difficult: acne, alopecia areata, cloasma, copaiha eruption, eczema, particularly pustular eczema of the scalp and mouth, iodine eruption, leprosy, lupus erythematosus, measles, psoriasis, urticaria, zoster, chancroid, gonorrhea, etc. The presence of the lesions of syphilis in connection with other skin diseases often made the diagnosis obscure, hence the necessity for the greatest care. Differential points were made.

The Committee on nominations reported: For President, A. L. Loomis; Vice-President, A. M. Phelps; Secretary, W. M. Smith; Treasurer, C. H. Porter.

DR. STOVER, of Amsterdam, described a modification of Chadwick's Gynecological Table.

A number of papers were read by title.

The Society adjourned at 10.50, A.M.

THE BOSTON

## Medical and Surgical Journal.

THURSDAY, FEBRUARY 17, 1887.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 283 Washington Street.

Remittances should be made by money-order, draft, or registered letter, payable to

CUPPLES, UPHAM & COMPANY,  
283 WASHINGTON STREET, BOSTON, MASS.

#### RIGHT-HANDEDNESS.

SINCE the time of Aristotle, and we are not aware how much longer, the cause of the superiority of the right side has been a repeatedly recurring subject for discussion. If all that has been written on the subject could be collected, the huge mass would be interesting in ways quite unconnected with the question in hand. It would show, as in a long panorama, the progress and vagaries of medical science, and of the methods of thought of the times.

The rise and fall of systems, the coming of new and more accurate knowledge, would all leave their mark. We should be able to recognize, in different ages, the chief types of minds: the rash, the plausible, the cautious, the mystical; the one so dominated by one idea that it can see no other side; and its opposite, to whom the truth and error of various views appear to counter-balance one another so accurately, that a decision is impossible. We should find, no doubt, during the reign of each prominent system, a line of inventors of the self-same theory, each unconscious both of his predecessor's light, and of the critic who snuffed it out, and unsuspecting that another is at hand to do as much for himself.

The paper that has thrown us into such a moralizing mood is a very interesting one on "Man's Aptitude for Labor in the Erect Position, with an Inquiry into Right-handedness," which Dr. Oscar H. Allis, of Philadelphia, read before the College of Physicians of that city a few months ago, the advanced sheets of which have lately reached us. The central idea of the essay is that man's easiest mode of supporting the centre of gravity during labor is by rotary motion. It may be that this action is not universal, but we agree with the author in so far as to admit that it is very general. He then argues that the mechanism of the skeleton shows special provisions for this kind of strain. We shall not follow him through his argument in support of this proposition, which cannot be well given in few words, but will admit that, though parts might be criticised, it amounts to a demonstra-

tion, and then pass on to the deductions concerning "the agencies that predispose to the very universal preference for the right leg and arm."

Dr. Allis holds that the cause is a mechanical one, and one that comes into play when the child begins to walk. This cause is the weight of the liver, which, from its asymmetrical position, brings the centre of gravity to the right of the median plane of the body, and, as he expresses it, "anchors the right side, gives it stability, and predisposes erect man to a preference for the right hand." Because the right leg is more firm, the arm of the same side is better supported. Moreover, according to our author, "rotary motion in the erect position requires that one hand should be principal, and the other assistant."

"In demonstrating the position of the liver, I have been in the habit of remarking that the great weight of that viscus on the right side does not appear to be balanced by the viscera on the left side. . . . The fact would be sufficiently interesting in relation to animal symmetry and equipoise, to visceral development, and to the mechanism of the erect posture; but it has lately assumed a new importance, from the theory that a greater weight on one side of the body will determine the greater strength and use of the limbs of that side, and thus furnish a physical explanation of the use of the right hand in preference to the left." No! these remarks were not written with reference to Dr. Allis's paper, as the reader probably supposes. They are from the pen of Prof. (then Dr.) John Struthers, and are to be found in the *Edinburgh Medical Journal* of 1863. They refer to the paper of Prof. Andrew Buchanan in the fifth volume of the "Proceedings of the Philosophical Society of Glasgow," who takes, as they show, essentially the same ground as Dr. Allis.

Although not assigning so important a part in the mechanics of the human body to rotary motions, Professor Buchanan repeatedly refers to them, and analyzes at considerable length the movements that concur in throwing a ball. He believes that the body does not turn on a central axis, but on one that is continuous with a line dropped from the centre of gravity, and, consequently, on the right. Dr. Struthers, in his paper, discussed some of Dr. Buchanan's statements on the effect of respiration on the position of the liver, and, by a series of careful calculations, settled a question which remained unanswered the other day at Philadelphia, to wit: that the viscera of the right half of the body are heavier than those of the left.

The reason, according to Professor Buchanan, why women carry babies and bundles on the left arm, is that the extra weight tends to counter-balance the liver, but that heavy burdens are put on the left shoulder for a totally different reason, namely, that the consequent lateral inclination of the body brings the weight over the stronger right leg.

According to this theory, the superiority of the right side depends on a purely mechanical cause, and is not the result of fashion or of education. The right arm is the strongest because it is used the most,

and there is no difficulty in supposing that the left side of the brain becomes more developed in consequence, and further, that these characteristics are inherited.

The most provoking jack-in-a-box which cannot be suppressed, but is jumping up at frequent intervals, is Hyrtl's theory that the right arm gets the stronger current through the innominate artery, and that in left-handed people the right subclavian is given off last. This is quoted, sometimes with the self-evident refutation which its weakness, incompleteness and imaginary origin demands, sometimes as a fact on the authority of the great teacher whose *ipsissima verba* are rarely spared us. It was let off last about a year ago by a writer in the *Medical Record*, who apparently thought that he was imparting information. It is plain that even if this theory had any foundation it would account directly only for the arm. Making due allowance for the physiology of two thousand years ago, Aristotle's theory is of broader application. "The right side is preëminent over the left because it receives, not only a more abundant supply of blood, but blood of a different quality, purer and hotter. The aorta with its branches supplies the left side, while the vena cava, which is larger than the aorta, and lies on its right, supplies the right half of the body.

Now there are three objections to all these theories:

*First*, if right-handedness has a gross mechanical cause, such as the position of the liver or the course of the innominate artery, to account for left-handedness, we must assume that there is a transposition more or less complete of the viscera.

*Second*, there is frequently a difference in acuteness of touch between the sides.

*Third*, there seems to be something analogous to right and left handedness in animals.

The first objection to these theories is almost fatal, unless it can be proved that visceral inversion exists in cases of left-handedness, and conversely that left-handedness occurs with transversion. Now we know very well that there is no visceral inversion in the left-handed people who are examined by scores in medical practice, and also that in many, if not in most cases, the subjects of visceral inversion are right-handed. Dr. Allis, when asked to account for left-handedness, said that the predisposing cause of a preference for one hand or the other is a little thing. The answer, if correct, is a refutation of his own theory.

The second objection is that these theories account at most for the greater size and more ready use of one side, and give no explanation of other important phenomena. Weber asserted long ago that tactile sensibility is greater on the right, but that the power to distinguish between different degrees of temperature and of pressure is greater on the left.

This line of investigation has been almost entirely ignored. With the exception of the report of a single case, in 1870, of a left-handed person whose greater sensibility to touch and to warmth were inverted, we know of no new observations until comparatively re-

cently in Italy. Most of the observations have been made on the insane and on criminals, and though we do not subscribe to the hobby that each of these is a class *sui generis*, we should not choose either for general statistics. In point of fact the observers have not done so, but have endeavored to draw comparisons between them and the rest of the community, yet so far as we know there have not been a sufficient number of observations on others to establish a rule. Professor Lombroso found that of 67 students (presumably neither insane nor criminals, or who at least had not been found out), twenty were left-handed in sensation, and eighteen right-handed. It would lead us into other questions to discuss the results in the two special classes, but we think it may be assumed that in at least fifty men of a hundred, one side is the better for sensation, and that this by no means necessarily is the same or the better one for motion.

The third objection is that there is a favored side in many animals. The more their habits are studied the more evidence is obtained that most animals that have prehensile extremities use a certain side by preference. Dr. William Ogle found that of twenty-three monkeys twenty were right-handed. A parrot cannot manage a nut with the beak alone; he supports himself on one leg while the other is used as an arm. The same observer found that of eighty-six parrots, sixty-three stood on the right leg and managed the nut with the other. We have satisfied ourselves that parrots almost invariably have a favorite side. With the more common perching birds the point is not so easily settled, still there are those who believe that individual birds sleep resting on one leg rather than on the other. But though there is good reason for believing that in many animals there is a favorite side, there is, as a rule, little regularity even among those of the same species as to which side it is; and when we consider how differently from man's their bodies are supported, what we may call the equilibrium theory seems unsatisfactory.

More than twenty years ago Dr. Moxon suggested that as man has but one attention for two sides it is devoted chiefly to one, which takes the lead in associated movements. Perhaps this theory might be extended to account for differences in perception also. Crude as it is, there is a germ of truth in it. Vertebrates have true lateral symmetry only in the very earliest stages of embryonic existence. Soon vascular asymmetry shows itself, preceding changes in the viscera by which they lose their primitive evenness. In some animals the asymmetry is striking, as in the lungs of serpents, the oviducts of birds, to say nothing of such exceptional forms as the pleuronectide; but even in those parts of animals which remain symmetrical in theory, there is a discrepancy in fact. The bones, for instance, of opposite sides are not equally large. One may be larger on the right and another on the left, so that apart from the hypertrophy consequent on greater use, it is hardly possible that the two sides should be quite alike. Man is symmetrical

in plan, but in actual life he is not. Something quite analogous is to be seen in plants. Take as an instance those climbing plants that grow in graceful spirals. Each family has its regular side and turns either to the right or the left, yet species are occasionally met with that turn in the opposite way, and again certain individual plants persist in describing spirals at variance with those of their species. In a word they are left-handed. Now it is evident that for a plant to grow in spirals it must have something that disturbs the equilibrium and inclines it to one side or the other, hence this asymmetry is no defect; and it has been argued that in the case of man distinct advantages accrue from the want of perfect symmetry both in the organs of locomotion and of sensation. It is probable that the cause lies deeper than in the coarse anatomical arrangements to which it is so often ascribed; a conclusion very possibly reached by some of Aristotle's critics.

#### HISTORY AND CLASSIFICATION OF THE MYELITIS.

ANY one who will take the pains to look into any standard work on practice of the earlier part of this century (Mason Good, or Gregory), will be struck by the paucity of notions respecting spinal affections. He will find entire absence of hosts of terms familiar to the students of medical literature of to-day. Even the word *myelitis* seems to have been unknown to Good, and was first employed by Harless in 1814. Good's whimsical natural history classification of disease, and his arrangement of all his symptoms under uncouth Latin functional denominations, will strike the reader of the present day as somewhat odd.

Abercrombie and Ollivier were the first to describe acute myelitis as an affection independent of meningeal changes, giving naked-eye observations of exceeding accuracy and minuteness. Sir Charles Bell and Magendie had just before discovered the functions of the spinal nerves, and the localization in the columns of the cord of the motor and sensory tracts. Thus far, however, the knowledge of the minute anatomy of the spinal cord was in an inchoate state. Pathology cannot make any advances till the pioneer sciences, physiology and histology, have cleared the way, and in the first part of this century the entire nervous system was a *terra incognita*.

The impulse had been given by a great organizing mind, Bichat, whose life-work, begun in 1797, was finished before the end of 1802. Bichat, by directing the attention of physiologists to the elementary tissues, and to the vital properties of the tissues, gave an incalculable stimulus to histological and physiological investigation. The subsequent contributions in the department of the nervous system alone, of such accomplished workers as Rostan and Andral, Lobstein and Rochoux, Cruveilhier and Renak, Romberg and Tuerck, Duchenne of Boulogne, and Brown-Séquard, Oppolzer and Mannkopf, Leydig, Westphall, Charcot,

Vulpian, Hayem, Frommann, Leyden, Luys, and Lockhart Clarke (to mention only a few of the principal authorities to whom we are indebted), have given tolerable completeness to our knowledge respecting the conditions of diseases of the cerebro-spinal axis.

The inflammations of the spinal marrow are no longer the simple affair that Abercrombie supposed them to be, nearly sixty years ago. The spinal cord has been found to be a somewhat complex structure, containing certain "systems," or apparatuses, besides a frame-work of connective tissue, the neuroglia, and inflammation may affect primarily any one, or all of these constituent parts (in the latter case being *diffuse*), and on this fact the modern classification is mainly based.

The most general conception of the spinal cord is that of an organ composed of connective tissue elements, binding together nervous elements (the grey matter and the white matter). The latter can easily be arranged into "*systems*" having special offices (the central grey matter with its anterior and posterior horns, the antero-lateral and posterior columns). The "systematized" portions are the true "parenchymatous" portions, containing conducting fibres and cells. The first great division of the myelites would therefore naturally be into the parenchymatous and interstitial. The first class might then be defined as "systematic myelites, beginning and propagating themselves by the nervous elements, localizing themselves in a particular system," (Grasset).

Practically, this is a useful division, which includes most of the chronic forms of myelitis, and the most common of the sclerosis. Of sub-divisions we have: (1) Myelitis of the white columns (fasciculated sclerosis), differentiated still further into sclerosis of the posterior columns (to which belong locomotor ataxia and sclerosis of the columns of Goll), and antero-lateral sclerosis, the latter comprising "spastic paraplegia," and lateral amyotrophic sclerosis; (2) Myelitis of the gray substance, that is, of the anterior horns and the bulbar nuclei; under these latter heads are comprehended the interesting affections known as atrophic infantile paralysis, acute spinal paralysis of the adult, and labio-glossolaryngeal paralysis.

Bearing in mind that the above forms may be secondary as well as primary, we come to the second great division of the myelites, the interstitial. According to some pathologists (notably Jaccoud), all the myelites are primarily interstitial, that is, beginning and propagating themselves by the connective-tissue, and secondarily, involving the parenchymatous elements. A true inflammation of the parenchyma of the cord, Jaccoud says, beginning with the nervous elements and remaining for some time limited there, is no more a fact of spinal than of cerebral pathology.

Other pathologists (Erb, Vulpian, Grasset, Dujardin-Beaumez, Spitzka, etc.) take the more probable view that myelites may begin in a primary irritation of the nervous elements. In the present state of our

knowledge, it is impossible to tell, either by the clinical signs or the post-mortem appearances, whether the myelitis in a given case was due to primary irritation of the neuroglia, or of the nervous elements. For convenience we may still adopt the French classification, and regard interstitial myelitis as including all the acute inflammations of the cord except the diseases known as acute atrophic spinal paralysis in the infant and adult.

A peculiarity of these interstitial inflammations is that they are diffuse. They are prone to invade indiscriminately all the regions of the cord, and this fact is in striking contrast with the tendency of the parenchymatous inflammations to remain localized in certain "systems," as portions of the white columns or central gray substance. A peculiarity of the acute inflammations is their tendency to end in one or more foci of softening, while the characteristic of the chronic myelitis is the thickening of the neuroglia and atrophy of the nervous elements which invariably follow. Both the acute and chronic forms may be circumscribed or invaded, and are subdivided accordingly; there are types with ascending or descending march; some forms are so acute as to be speedily followed by death (apoplectic form type), others sub-acute, or chronic with very gradual march of the lesions. The region of the cord affected gives the name to certain varieties, (cervical, dorso-lumbar, etc.) and there is a special form of myelitis which is diffuse after a manner peculiar to itself, a form which is almost unique in pathology, namely multiple, or disseminated sclerosis.

The principal landmarks in the history of the myelites are as follows:

The term myelitis first appeared in the works of Harless (1814), and Kloss, (1820).

Ollivier, in 1821, and Abercrombie, in 1828, gave the first lucid description of this disease, pointing out the connection of softening with the acute forms of myelitis. In 1851 Romberg published his admirable treatise on "*Tabs Dorsalis*," in which the principal symptoms of the disease are enumerated, and the complete differentiation from the true paralytic diseases is effected; this epoch-making book was followed, in 1854, by Wunderlich's more full description. Tuerck, in 1858, announced his important discoveries concerning the primary and secondary degenerations; while Duchenne, of Boulogne, in 1858 and 1859, in memoirs which are classical, again called attention to the complex of symptoms characterizing posterior spinal sclerosis, which he was first to name *progressive locomotor ataxia*, giving a far more complete clinical account of that disease than has before been given. He was followed by Bourdon and Luys in 1861, who added to Duchenne's clinical description the data of pathological anatomy that were wanting.

The clinical history of multiple sclerosis begins with the work of Frerichs in 1849, and the pathological anatomy was cleared up by Rindfleisch (1863), by Leyden (1863), and Zenker (1865). Drawings, how-

ever, which are faithful reproductions of the lesions of insular sclerosis, appear in Cruveilhier's atlas (1835). Charcot and Vulpian have since contributed largely to our knowledge of this affection. For our knowledge of *tabes dorsalis spastica* we are almost entirely indebted to Charcot and Erb.

Jacob Von Heine, in 1840, was the first to call attention to the congeries of clinical characters which distinguish that myelopathy which he named "acute spinal paralysis of infancy." Duchenne, of Boulogne, in 1855, referred this affection to a lesion of the spinal marrow; and Cornil (1863), Prevost and Vulpian (1865), Lockhart Clarke (1868), and Charcot and Jouffroy in 1870, made valuable additions to our knowledge of the malady. The identity of this affection with the atrophic paralysis of adult life was shown by Moritz Meyer in 1869, and has been placed beyond doubt by the subsequent contributions of Charcot, Bernhardt, Kussmaul, Frey, Lincoln of Boston, Leyden, Erb, and Hammond.

Acute ascending paralysis was first described by Landry in 1859, and from that time reports of cases of this disease have been accumulating; we are still, however, in the dark as to the nature of the anatomical lesions in the cord which constitute this rapidly-progressive and fatal affection.

#### ANOTHER DIPLOMA MILL.

The *Boston Herald*, of February 11th, contains an account of the manner in which one of its reporters obtained a degree of M.D., from the "Druidic University of America, State of Maine Branch." The "University" is situated in the city of Lewiston, Me., and occupies a two and a half-story wooden building, which is ornamented with the sign of "Dr. Samuel York, Druidic Physician." The reporter represented himself as a young man who wished to settle in the city of Mexico, and there practice medicine in all its branches. With many assurances that the college did not sell its diplomas, the proprietor exchanged a matriculation ticket and a most elaborate diploma for a small amount of money, which was said to cover cost of printing and other expenses. The aspirant was also put through some very farcical examinations, and given some equally absurd instruction, the whole transaction covering some six hours' time within three different days.

An act incorporating the Maine Electric Medical Infirmary was passed by the Maine Legislature of 1871, and in 1880 was incorporated the "Penobscot Valley Gorsedh of Bards and State of Maine Branch of the Druidic University of North America, for the purpose of promoting literature, science, art, medicine, philosophy, and other branches of knowledge and industry, according to the graded and seven year's curriculum of the bards," etc. Both infirmary and university are domiciled in the wooden structure already mentioned, although no accommodations for patients were visible, nor means for instruction other

than a skeleton and a few miscellaneous bones, an antiquated electrical machine and a copy of Neil and Smith's Compend of Medicine, edition of 1864. The diploma was elaborate, however, in "double and twisted" Latin, as stated by the vendor, with the addition of certain phrases which resemble Welsh.

The fact that such institutions can be incorporated and do business under the laws of Maine, shows that either the Maine laws regulating corporations are very lax or that the lawgivers of the State are somewhat careless in their attention to matters before them.

In an interview, subsequent to the *Herald's* exposure, with a Lewiston reporter, "Dr." York pretended to regard the matter as a good joke, and denied selling a diploma, saying that the document was only a copy of a society diploma, an allegation which the document itself does not support. At this latter interview a degree from the famous Buchanan University, seen by the *Herald* reporter, had disappeared from the Druidic Doctor's walls.

The exposure has already been followed by action on the part of the Maine Legislature, which has in view the repeal of the charter of the Druidical University. Legislation should also provide for the future, that the legal existence of such institutions may no longer be possible.

#### MEDICAL NOTES.

##### BOSTON.

—The Committee on Public Health of the Massachusetts Legislature consists, on the part of the Senate of, Jubal C. Gleason, M.D., Rockland; Edward J. Jenkins, Boston; Edward Glines, Somerville. On the part of the House: Theodore Giddings, M.D., Great Barrington; Samuel B. Bird, Framingham; John Larrabee, Melrose; Daniel J. Maguire, Boston; Luther Conant, Acton; Jonathan Bigelow, Watertown; James Sullivan, Boston; Felix F. McCue, Montague. This Committee has at present before it the question of lowering the standard for pure milk.

##### NEW YORK.

—Dr. D. G. Brinton, of Philadelphia, who has recently been elected Professor of American Linguistics and Archaeology in the University of Pennsylvania, recently delivered a lecture before the New York Historical Society on "American Aboriginal Poetry."

—The Committee on Books and Newspapers of the State Charities Aid Association report that, during the past year, they distributed in hospitals and other institutions over 95,000 daily newspapers, 22,500 illustrated and weekly papers, 8,000 magazines, 2,800 bound books, and 5,000 Christmas cards.

—A legal case arising from railway injury in Troy, has just been finally decided by the Court of Appeals, after seventeen years of litigation. In April, 1870, the plaintiff, then a girl of ten years, was run over by the New York Central and Hudson River Railroad cars, while crossing an alley, and one of her legs was so badly crushed that two successive amputations

above the knee were required. The case has been tried four times in the Circuit Court in Troy, and seven appeals to the General Term and to the Court of Appeals have been taken by the unsuccessful party for the time being. In the fourth trial, the jury gave a verdict of \$7,500 for the plaintiff, and this has now been sustained by the Court of Appeals. The cost to the defendant, including interest, extra allowance, and court charges, is nearly \$20,000.

#### PHILADELPHIA.

—The Alleghany County Medical Society has voted an appropriation of one hundred dollars towards the expenses of the international Medical Congress, at Washington. Other County Medical Societies are preparing to follow this example.

—A death, last week, during the administration of chloroform at one of our College clinics, may serve as a text for repeating the old homily on the dangers of anesthetics. As usual, the chloroform was administered for a trifling operation, breaking up some adhesions after syngitis of the wrist; and, as usual, the patient was moribund before attention was attracted to symptoms indicating danger. The coroner's jury found that the patient had a fatty heart, and exonerated the physicians, but the stubborn fact remains that he died during the administration of chloroform. It would seem only a reasonable precaution for each hospital to have an experienced anesthetizer upon its staff, who should be intelligent enough to appreciate the responsibilities involved, and sufficiently trustworthy to assume them.

—The draught of an Act creating a State Board of Medical Examiners, prepared by a Committee of the State Medical Society, was submitted to the Philadelphia County Medical Society, recently, and favorable endorsement refused on account of the composition of the proposed Board, which was to be "mixed." There is a strong feeling that there should be some attempt to protect the community from ignorant and incompetent physicians, by the State. The registration law has done some good since it compels the showing of credentials, but this is but a slight gain. It is felt that some form of license to practice should be demanded, and that dependance upon the diploma as an evidence of fitness is a poor substitute for a State examination. Something of this kind is already required in the case of physicians who come into Pennsylvania with foreign diplomas, since it has been ruled by the Supreme Court that the Faculties of our Medical Schools "must satisfy themselves of the qualifications of the applicant," before endorsing the diploma, as required by the Act of June, 1881.

—While on the subject of legislation affecting the interests of the medical profession, it should be noted that the druggists are advocating a bill to advance pharmacy. It seems, however, that by its provisions a druggist is allowed to practice medicine so long as he confines himself to prescribing over the counter, and charges no specified fee, although he may demand

his own price for medicines furnished. There are also some restrictions placed upon physicians which, to say the least, are not demanded by the profession. Strange to say, an appeal is circulated among physicians for their signatures in favor of the passage of this law.

—The operation of excision of the larynx for malignant growth was performed at the Hospital of the University of Pennsylvania, on the 2d inst., by Prof. D. Hayes Agnew. The patient was a man, sixty-five years of age, of fair health but of rather intemperate habits, who six months ago applied to Dr. J. Solis Cohen, for some difficulty in his throat. A tumor of small size was discovered upon the upper portion of the arytenoid cartilage of one side; subsequently this steadily increased, until at the time of operation it was as large as a walnut. It grew upwards into the pharynx and had not encroached upon the glottis. Its surface was smooth, and it presented the appearance of sarcoma. The patient was fully etherized, and an incision made along the front of the thyroid cartilage and trachea. Preliminary tracheotomy was not performed; but the trachea was dissected for a short distance from the œsophagus, so that a ligature could be passed around it. The trachea was then cut across, and a silver tube, bent more acutely than those generally used, was slipped into a piece of rubber-tubing and the whole passed into the trachea, fitting it like a cork in a bottle; the ligature was then fastened so as to keep it in place. A piece of soft rubber-tubing was then attached to the free end of the tracheotomy tube, and a peculiar apparatus affixed to it. A funnel had its broad extremity covered with wire gauze, then a piece of flannel was laid over this, upon which the ether was dropped. This answered admirably for maintaining anesthesia during the operation. The remainder of the operation consisted in dissecting the larynx free from its attachments, dividing the epiglottis at its beginning, and removing several inches of the pharynx which appeared infiltrated. The wound was dressed antiseptically. The patient was nourished by means of an œsophageal tube. Dr. Formad, after examining sections of the growth, pronounced it epithelioma. The patient died on the fourth day after the operation, from exhaustion.

### Correspondence.

#### THE DOCTOR'S MESSAGE AGAIN.

NEW YORK, February 7th, 1887.

MR. EDITOR.—In your issue of February 3d, "B" wants to know what the Greek sentence on his office slate meant. The translation is "My relatives wish me to go home." But, goodness gracious! *τίς αὖτις ἐθέλησεν τὰς γὰρ ἐν Βοστώνῃ καμνοῦσι σὺν ἡμῖν τὰ τοιαῦτα ἐλλογιστὶ διαλέγεσθαι.*

Yours respectfully,

ROBERT T. MORRIS.

[For the benefit of the physician who failed to understand the message on his slate, a translation of the above

is appended: "We certainly supposed the sick in Boston were in the habit of speaking Greek with their physicians."—Ed.]

ST. LOUIS, 507 N. 14th St.

February 8th, 1887.

MR. EDITOR.—In reply to your correspondent "B," whose article appears in your issue of February 3d, requesting a translation of the following Greek sentence left on his table by some patient, I send my contribution. The sentence was "οι ἀρχαῖοι, ἐπὶ τῶν νοσούντων ἵσταντο τὴν ψυχὴν." To translate this may require some little thought, as it seems to be in the Attic dialect. "My necessities (the Fates, or my relations) require me to go home," is the way I should render it. Your subscriber "wonders how many of your readers can translate this sentence." I should

suppose it would be quite unnecessary to go out of Boston for a translation, but that every medical graduate of Harvard University ought to be able to translate it. In the opinion of the undersigned (a constant subscriber of your valuable JOURNAL for more than twenty years past) no one should be allowed to graduate as a doctor of medicine until conversant with the classic tongues.

Very truly yours, T. G. C., M.D.

EAST BOSTON, February 10th, 1887.

MR. EDITOR.—I would suggest as a translation to your Greek correspondent, "I cannot wait any longer;" or, more literally, "Necessity obliges me to go home." I hope the doctor will have the good fortune to see that patient; he is truly a *rara avis*.

Yours respectfully,

A READER.

REPORTED MORTALITY FOR THE WEEK ENDING FEBRUARY 5, 1887.

Deaths reported 1,662: under five years of age 614; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases whooping-cough, erysipelas and fevers) 315, acute lung diseases 268, consumption 240, diphtheria and croup 108, measles 90, diarrhoeal diseases 23, typhoid fever 27, whooping-cough 12, scarlet fever 10, puerperal fever 10, malarial fever nine, small-pox eight, erysipelas six, cerebro-spinal meningitis five. From typhoid fever, Baltimore six, New York, District of Columbia and Pittsburgh four each, Boston three, Lowell two, Providence, Worcester, Lawrence and Chelsea one each. From whooping-cough, New York eight, Pittsburgh two, Baltimore and New Orleans one each. From scarlet fever, New York five, Boston, Portland, Pittsburgh, Providence and Brockton one each. From puerperal fever, New York, Pittsburgh and Providence two each, District of Columbia, Lawrence and Waltham one each. From malarial fevers, New York four, Baltimore three, New Orleans and District of Columbia one each. From erysipelas, New York four, Boston two. From cerebro-spinal meningitis, Boston and Fall River two each,

New York one. From small-pox, New York seven, Pittsburgh one.

In the 18 cities and greater towns of Massachusetts, with a population of 943,711 (population of the State 1,941,465) the total death-rate for the week was 18.95 against 22.45 and 20.74 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,345,099, for the week ending January 23d the death-rate was 22.8. Deaths reported 4,043: infants under one year of age 789; acute diseases of the respiratory organs (London); 531; measles 146, whooping-cough 92, scarlet fever 62, diarrhoea 36, fever 33, diphtheria 23.

The death-rates ranged from 15.0 in Derby to 33.8 in Plymouth; Birmingham 23.7; Hull 21.5; Leeds 28.4; Leicester 19.0; Liverpool 26.4; London 21.8; Manchester 30.1; Newcastle-on-Tyne 26.3; Nottingham 22.3; Sheffield 19.3; Sunderland 22.5.

In Edinburgh 23.2; Glasgow 27.8; Dublin 32.2.

The meteorological record for the week ending February 5, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending	Barom-eter.	Thermometer.		Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather.			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM FEBRUARY 5, 1887, TO FEBRUARY 11, 1887.

FEYER, BLENCONE E., major and surgeon. Ordered to Fort Lowell, Ariz. Ter. S. O. 29, A. G. O., February 4, 1887.

LOBBING, L. Y., captain and assistant surgeon. Leave of absence still further extended three months on surgeon's certificate of disability. S. O. 29, A. G. O., February 4, 1887.

BRECKENSHIN, LOUIS, captain and assistant surgeon. Granted leave of absence for four months, with permission to go beyond sea, to take effect when his services can be spared by his department commander. S. O. 28, A. G. O., February 3, 1887.

BARROWS, C. C., first lieutenant and assistant surgeon. Ordered for temporary duty as post surgeon at Fort Barrancas, Fla., to take effect upon the expiration of his present leave of absence. S. O. 24, Division of the Atlantic, February 3, 1887.

PHILLIPS, JNO. L., first lieutenant and assistant surgeon. Leave of absence further extended one month. S. O. 29, A. G. O., February 4, 1887.

WOOD, LEONARD, first lieutenant and assistant surgeon. Ordered to proceed to these headquarters and report to the department commander, for temporary duty. S. O. 12, Department of Arizona, January 31, 1887.

#### SOCIETY NOTICE.

NORFOLK DISTRICT MEDICAL SOCIETY.—A meeting for Scientific Improvement will be held at the hall of the Roxbury City Guard, 67 Warren Street, Roxbury, February 22, 1887, at 7.45, P. M. Communications: I. "Remarkable Hypertrophy of the whole Right Leg, with Exhibition of the Case," F. C. Martin, M.D. II. "Experimental Research on Rabies," H. C. Ernst, M.D. III. "A Case of Intra-Orbital Abscess," W. S. Everett, M.D. S. ALLEN POTTER, M.D., Secretary.

#### APPOINTMENT.

Dr. J. W. Pratt has been elected Superintendent of the Massachusetts General Hospital.

#### OBITUARY. EZRA DYER, M.D.

Dr. Ezra Dyer, whose death on February 9th, has just been announced, was formerly a resident of Cambridge, and graduated at Harvard, in the class of 1857. He studied medicine with the late Dr. Jeffrey Wyman, and after passing a year as House-Surgeon at the Massachusetts General Hospital, sailed for Europe in the autumn of 1859. Remaining at Bonn a few months, for the purpose of familiarizing himself with the German language, he reached Vienna before the close of the year, and there decided to devote his entire attention to the study of ophthalmology; which science, thanks to the recent labors of Graefe, Arlt, and Donders, had just been re-created. These illustrious masters were then in their prime, and Dr. Dyer, for the next two years, followed their personal teaching, dividing his time, for this purpose, between Vienna, Berlin and Utrecht. He also entered the clinique of Desmarres at Paris, and came to London for the advantages to be derived from attendance at Moorfields, where Bowman and Critchett were at the height of their fame.

Returning to this country in the latter part of 1861, he settled first in Philadelphia, where his services were almost imme-

diately engaged in the ophthalmic department of the government military hospital at West Philadelphia, and where, too, he rapidly built up a successful practice. Some years later the health of a member of his family obliged him to seek a change of climate, and he removed to Pittsburgh. While there he met with a severe accident, and his own health having been seriously affected by the shock, as well as by the confinement he was obliged to undergo, he again removed to Newport, R.I., by the advice of his physicians. But he failed to gain the benefit he had hoped from the more genial air and milder climate of this resort, his strength slowly failed, and he died at sea, on the voyage from Savannah to New York, while returning from a brief excursion to Florida.

Dr. Dyer was one of the original members of the American Ophthalmological Society, and his name was a household word in the annals of this branch of surgery in the United States. Among his many services to science we have here only space to allude to the beautiful and ingenious perimeter, figured in the last volume of the Society's Transactions, and more especially to his discovery of the proper treatment of simple asthenopia, which under the name of "morbid sensibility of the retina," had been the despair of ophthalmic surgeons for one or two generations. His method of gymnastic training of the eye, the conception of which was due to his own experience as a trainer for athletic contests during his undergraduate days, revolutionized practice in this affection; gave a large percentage of successful results, and under the name of "Dyerizing," is widely known and generally appreciated at home and abroad.

To this hasty and imperfect notice a single word must be added. For thirty years past the writer has had the privilege of Dr. Dyer's personal and intimate friendship. He has realized, as few others could, the rare combination of clearheaded judgment, generous frankness and simple loyalty that made up his character. He was in the truest sense a friend in need; devotion and unselfishness personified. May he rest in peace.

H. D.

#### BOOKS AND PAMPHLETS RECEIVED.

Wear and Tear; or Hints for the Overworked. By S. Weir Mitchell, M.D., LL.D., Harv. Fifth Edition. Thoroughly revised. Philadelphia: J. B. Lippincott Co. 1887.

On Antiseptic Surgery and its Application in Military Hospitals and in the Field. By Surgeon Major John Martin, Army Medical Staff. London: J. & A. Churchill. 1886.

Clinical Manual for the Study of Medical Cases. Edited by James F. Halcyon, M.D. Second Edition, Revised and Enlarged with 158 Illustrations. Philadelphia: Lea Brothers & Co. 1886.

Zur Pathologie und Hydrotherapie der Cholera. Von Prof. Dr. Wilhelm Winternitz unter Mitwirkung der Herren Dr. L. Schweinburg, Dr. J. Pollak und Dr. J. Utschik. Leipzig und Wien, 1887.

Texas State Medical Association. Report of the Special Committee. Presented at the Annual Meeting at Dallas, April 27, 1886. George Cupples, M.D., Chairman and Reporter. Austin, Texas, 1886.

Diseases of the Joints. By Howard Marsh, F.R.C.S., Senior Assistant Surgeon to and Lecturer on Anatomy at St. Bartholomew's Hospital, etc. With 600 illustrations and a colored plate. Philadelphia: Lea Brothers & Co. 1886.

A Treatise on Simple and Compound Ophthalmic Lesions, Their Refraction and Dioptric Formulae. Including Tables of Crossed Cylinders and their Sphero-cylindrical Equivalents. By Chas. F. Prentice. Published by James Prentice & Sons, New York.

## Lecture.

MULTIPLE NEURITIS AND ITS RELATION TO CERTAIN PERIPHERAL NEUROSES.<sup>1</sup>

BY M. ALLEN STARR, M.D., F.R.C.,  
Professor of Nervous Diseases, New York Polytechnic.

## III. SPONTANEOUS CASES.

Is a considerable number of cases of multiple neuritis no cause of the disease could be definitely ascertained. Great fatigue by walking, or by hard labor and exposure to dampness and cold, are assigned as causes in some of these cases, and may have acted as etiological factors. In others the disease seems to have developed spontaneously.

*Symptoms.* Turning now to the consideration of the individual symptoms of multiple neuritis and their course, we are at once impressed by their number and variety.

The *sensory symptoms* are the earliest to appear and the last to pass away. In the majority of the cases on record, from whatever cause, numbness, tingling, or formication usher in the disease. These forms of paræsthesie begin in the feet and hands, and extend to the knees and elbows. They may be associated with burning, stretching, boring, or tearing sensations, which distress the patients, especially during the onset. But all such sensations usually subside as the affection reaches its height. Their recurrence, as the case goes on, may be regarded as a favorable symptom, however annoying, for they frequently precede recovery, and are among the last evidences of the disease to disappear. Pain is usually present as well as paræsthesie. It may occasionally be sharp in character; but is usually moderate and not continuous. At times it may be lancinating, and so severe as to necessitate the use of morphia. But it is rarely as distressing as in cases of locomotor ataxia. Tenderness in the nerves and muscles is a constant symptom. It may be so marked that the limbs cannot be moved or handled, and thus it may interfere with the application of electricity and massage. When the tenderness and pain are referred to the joints, as not infrequently occurs in the early stage of the disease, the case may be mistaken for one of acute articular rheumatism, and if the joints are swollen or the limbs œdematous, the difficulty of diagnosis is greatly increased.

In addition to these subjective feelings, some demonstrable disturbance of the various sensations is usually present. Hyperæsthesia to touch, and also to electricity, is not infrequently observed during the first few weeks. It is usually followed by some anæsthesia, although this rarely becomes complete. In some cases the loss of tactile sense is quite evident from the outset, either limited to the cutaneous distribution of some special nerve, in which case oddly-shaped areas of insensibility will be found, or, as is most often the case, about uniformly distributed over the distal parts of the extremities. When the anæsthesia is at its height, the patient has difficulty in locating a touch upon the limb, even though he feels it. The transmission of pain and temperature sensations is always delayed, but the impressions are usu-

ally felt quite acutely. The sense of pressure has been tested in only a few cases, and in those it was decidedly impaired. The muscular sense escapes any affection in some cases, but in others is the most profoundly disturbed of all the senses. When it is involved, the incoördination and ataxia are well-marked symptoms, and, as already stated, some of the cases have been mistaken for locomotor ataxia, because of the predominance of the disturbance of muscular sense.

These sensory symptoms are usually limited to the forearms and hands, and to the legs and feet. In a few cases they have involved the entire extremities, and even the trunk; and one case of facial tingling with anæsthesia has been recorded. The skin reflexes are usually preserved.

The special senses are rarely affected in multiple neuritis. It is true that optic neuritis has occurred in a few cases, and in two cases hearing as well as sight has been affected. These cases prove that no nerve can be said to be exempt from implication in this disease, but the liability to affection seems to be slight in the case of the nerves of special sense.

The *motor symptoms* are as marked and as important as the sensory. Paralysis, beginning as simple weakness, with a feeling of fatigue on any exertion, gradually increases in severity until, at the height of the disease, it becomes complete. It usually comes on rapidly, so that within two weeks the patient is helpless; but it may be less sudden, and not deprive him of the power of walking and of using his hands for two or three months. In a few cases a very acute onset is recorded, all the symptoms developing within three or four days. The distribution of the paralysis is not uniform at the outset. It may develop in the muscles supplied by a single nerve, and advance to others; it may begin in all the muscles of the legs, and then involve those of the forearms; it may commence in all four extremities at once. It is always more severe in the muscles which move the joints of the feet and hands, and the ankles and wrists. It rarely invades those which move the knees and elbows. When the disease is fully developed all the muscles below the knees and elbows are much weakened or totally paralyzed. In a few cases those of the thighs and arms are involved also, and occasionally the muscles of the trunk and those of respiration become affected and the patient dies. When such a paralysis makes rapid progress and involves all the body, the case resembles Landry's paralysis. But in multiple neuritis, as has been already stated, the disease does not creep up from legs to thighs, and then trunk and arms, as in Landry's paralysis. It spreads from feet to hands, from legs to forearms, and the trunk is invaded only at the end. In some cases of multiple neuritis the cranial nerves become involved; those of the eye and of the face being most liable to invasion. It is only in fatal cases that the action of deglutition has been affected; and when the pneumogastric is invaded, and the heart becomes rapid and irregular, the prognosis is always grave.

The paralyzed muscles are relaxed, flabby, and atrophied; they may or may not lose their mechanical irritability, but their normal tone is always lost, and hence the so-called tendon reflexes are abolished. To the electric current their excitability is very rapidly and markedly changed; but the conditions which have been observed are quite various. Some-

<sup>1</sup> Lecture II (concluded from page 154) of the Middleton Goldsmith Lectures, delivered under the direction of the New York Pathological Society, Jan. 28, 1887. For Lecture I, see page 161 of the Journal.

times there is a simple diminution of excitability, and then a very strong faradic or galvanic current is needed to produce contractions. Frequently all faradic excitability is lost, and then the muscles react to a galvanic current only. In this condition it may require a very strong galvanic current to produce contraction, and this fact is quite pathognomonic of neuritis. For an anterior polio-myelitis, where the muscles respond to galvanism only, it does not require a strong current to cause a motion until some months after the invasion. The action of the different poles is not uniform. In many cases the contraction of the muscle, when stimulated with the positive pole, is greater than when stimulated with the negative pole, and the contractions may be sluggish. Then the reaction of degeneration is present. But in some cases the normal condition is found, and the negative pole produces stronger contractions than the positive pole. If the muscles that are not paralyzed be tested, the same electrical changes may often be discovered in them. A loss of faradic irritability and a marked decrease in the galvanic irritability of the muscle and nerve are, therefore, important symptoms of multiple neuritis. And as the disease goes on to recovery, a gradual increase in the galvanic irritability occurs, a fact which is often of much aid in prognosis if careful measurements of the strength of current used be made by the galvanometer. I am accustomed to record such measurements upon charts, and thus to obtain an electric curve for each muscle which is paralyzed. These curves enable one to judge of the progress of the case quite accurately; and when the line is advancing steadily toward the normal point, after a great deflection or after a stationary level, the prognosis is very favorable.

As a result and accompaniment of the paralysis, *abnormal positions* are assumed by the limbs. The dropped wrist and dropped foot are quite characteristic of multiple neuritis. But other deformities may be present. In a few cases it has been necessary to resort to tenotomy, but a permanent deformity has not been recorded.

The *vaso-motor and trophic symptoms* are less constant than those already described. In some cases, marked oedema has been an early and permanent symptom. Sometimes profuse perspiration is a noticeable symptom, being limited to the paralyzed parts. It may be offensive, and by its evaporation always causes a complaint of coldness. In other cases glossy skin makes its appearance early, and remains until regeneration of the nerves begins. Its disappearance, in one of my own cases, was the first sign of recovery in the lower extremities. Other forms of trophic disturbance are rarely met with in multiple neuritis. And this is quite remarkable, in view of the fact that it has been the tendency of late to refer such trophic affections as ulcerations, bed sores, gangrene, pemphigus, and various eruptions, to lesions of the nerves.

A negative symptom of some importance is the absence of any interference with the automatic acts controlled by the sphincters.

One word about the onset. Occasionally it is sudden and accompanied by a marked febrile movement, with chill, and temperature of 103° to 104.5°. The fever may persist for several days, but usually subsides spontaneously, and does not recur. In a few cases there has been a constant elevation of temperature from one-half a degree to one and a half degree

above the normal; and an increase in the rapidity of the pulse throughout the disease has been noticed. A pulse of ninety need give no alarm, but if it runs up to one hundred and forty, and becomes irregular, there is reason to believe that the disease has attacked the vagus nerve, and then the prognosis becomes serious, though not by any means hopeless.

The duration of the disease varies considerably in different cases. An average of twenty-five cases gives seven months as the probable time required for complete recovery. But in these cases the duration varied from two months in the most favorable, to sixteen months in the most refractory.

The disease is more common in males than in females, excepting the form produced by alcoholism. Of 47 non-alcoholic cases, 33 were males.

All ages are liable to be affected, but in the records of multiple neuritis, excepting the form produced by diphtheric poison, the cases recorded do not include any children.

That children may be affected is, however, not at all improbable. Dr. H. D. Chapin, of New York, has described four cases of atrophic paralysis in children, in which the presence of sensory symptoms, pain, and muscular tenderness, and the steady progress toward recovery, pointed to the existence of multiple neuritis. The cases were such as are usually called infantile paralysis, but there were points of difference (namely, the existence of sensory symptoms) which removed them from this category.

*Diagnosis.*—While the individual symptoms occurring in the course of multiple neuritis are not different in character from those found in spinal cord diseases, the diagnosis can usually be reached with very little difficulty when their combination, the causation, and the course of the case under examination are considered. The varying combination of the symptoms possible has been manifest during their description, and it is not my intention to review them again. There are, however, three combinations which resemble very closely, respectively, anterior poliomyelitis, locomotor ataxia, and diffuse myelitis, and to these attention must be directed. Atrophic paralysis, with reaction of degeneration and loss of reflex, is common to anterior poliomyelitis, and some cases of multiple neuritis. In the latter, a more gradual onset, preceded and attended by numbness and pain, tenderness in the course of the nerves, tenderness in the muscles, and the persistence of sensory symptoms after the invasion, will remove all doubt regarding the diagnosis. When these symptoms are not clearly marked, the distribution of the paralysis in symmetrically situated muscles, especially if these muscles are supplied by single nerves, and the further extension to muscles in other nerve domains, rather than the affection simultaneously of muscles which are grouped physiologically (that is, act together to perform one function), will point to neuritis. In neuritis the paralysis advances more or less gradually, while in acute poliomyelitis there is, after the onset, a subsidence of the paralysis in some of the muscles first involved. And lastly, as the case goes on, a gradual complete recovery will be far more frequent if it was originally a case of multiple neuritis.

Ataxia, loss of knee-jerk, pain, and sensory disturbances, including a loss of muscular sense, Romberg's symptom, and optic neuritis, are common to locomotor ataxia and multiple neuritis. In the latter, the relatively rapid onset of the ataxia, which follows closely

upon the sensory symptoms; the prominence of numbness and anesthesia, rather than of lightning pains; the extreme degree of the anesthesia and analgesia; the tenderness of muscles and nerves; the usual occurrence of some degree of actual paresis, with atrophy and R.D.; and the absence of bladder and sexual symptoms, will point inevitably to the diagnosis. Furthermore, the ataxic form of neuritis only occurs after poisoning with alcohol or arsenic, or as a sequel of diphtheria, and the establishing of the causation will aid the diagnosis. Here, again, the course of the case toward recovery, with the return of the knee-jerk, will decide in favor of neuritis, if the diagnosis has not been reached in an early stage.

There are very few symptoms of diffuse myelitis which are not found in cases of neuritis. But cases of diffuse myelitis of the type of Duchenne, *paralyse générale spinale subaigue ascendante*, are very rare, and indeed, by Leyden it has been affirmed that all such cases are multiple neuritis. Other authorities dispute this assertion, and leave us to establish points of difference. These are as follows: In neuritis, affections of the functions of micturition and defecation do not occur. Girdle sensation is very rarely mentioned as a symptom. Bed-sores and cystitis have not been observed. The advance of the paralysis from the legs to the thighs and trunk, and then to the arms; it is usually from the legs to the forearms, the thighs and trunk escaping, and, as a rule, the distal portions only of the extremities are paralyzed. If the muscles of the abdomen and respiration are involved, it is only in rapidly fatal cases. In neuritis there is usually some ataxia, and loss of muscular sense is quite evident; while in some, at least, of the cases of myelitis of Duchenne, there were no sensory symptoms at all. Finally, the tenderness of muscles and nerves, and the absence of tenderness to pressure or to heat in the spine, would decide in favor of neuritis. The diagnosis from meningitis of the cord, from tumors or hemorrhages into the cord, or from general paralysis of the insane, would rarely present any difficulty to one who was familiar with the symptoms in those affections, and who knew the prominent features of multiple neuritis.

No small difficulty may be encountered, however, in settling the question whether in a given case we have to deal with multiple neuritis alone, or with multiple neuritis which is complicated by myelitis. The importance of the question is evident, since the prognosis in the two conditions is very different. And the number of autopsies on record in which this complication has been demonstrated, though few, is sufficient to make a decision of the question necessary. The following points may enable a determination of the question to be reached: (1) As long as a case is increasing in severity, or in the extent of the symptoms, no one can determine the extent of the lesion. It is only when its course has become stationary that the question of exact limitation will arise. Many cases remain practically without improvement for three or four months, and then gradually recover. A stationary condition alone does not, therefore, excite fear of a complication. But neuritis tends spontaneously to recover, the process of regeneration beginning soon after the degeneration has ceased. If, therefore, there appears to be no improvement of the condition after the fourth month, the probability is either that the cause of the disease has not been removed, or that

a myelitis has developed and prevents recovery. (2) The cause of a case of neuritis is quite characteristic, the symptoms reaching their maximum in a short time, and then subsiding. If, after a stationary period, further symptoms develop, we must believe either that the cause of the disease is renewed (for example, the use of alcohol) or that myelitis has begun. The symptoms of such a myelitis will be an increasing weakness, and more rapid and progressive atrophy of the muscles; a gradually-decreasing degree of galvanic excitability in the paralyzed muscles; a loss of pain and temperature-senses, which, as a rule, are not affected in neuritis; a decrease in the parasthesia, and an increase in the degree of anesthesia; the development of loss of control over the sphincters; the occurrence of bed-sores, furuncles, eruptions of a bulbous nature, and the beginning of cystitis. (3) On the other hand, if the symptoms are gradually improving; if the power gradually returns; if the anesthesia decreases, and is succeeded by parasthesia, however disagreeable to the patient; if the galvanic excitability becomes gradually more acute in the muscles, so that the electric curve approaches the normal line; if the faradic contractility returns in the muscles; if the tenderness of muscles and nerves decreases; and if the glossy appearance of the skin disappears, it may be stated that no complication of myelitis has occurred, and that recovery, though possibly prolonged, will at length result.

Another question of diagnosis must also be considered. It is found that in no small number of cases of locomotor ataxia multiple neuritis develops as a complication. How can we determine when this complication exists? The symptoms of the two diseases may be so nearly identical that difficulty arises in distinguishing them. When they coincide it is equally difficult to determine to which any given symptom belongs. Pitres and Vaillard, who have considered this subject most carefully, affirm that there is no constant relation between the severity of the central and peripheral lesions when they coincide. But there are certain symptoms which develop in some cases of tabes, but not constantly, which may be looked upon as accidental, and thus traced to neuritis. Such are the appearance of plaques of anesthesia and analgesia of limited area, muscular weakness or paralysis of limited extent, trophic disturbances in the skin (for example, perforating ulcer), nails, joints (for example, Charcot's disease), bones (for example, spontaneous fractures), and teeth (for example, spontaneous falling out), and possibly the various crises referable to the viscera and larynx. In cases which competent observers have examined, peripheral neuritis has been found *post-mortem* in the nerves supplying the parts in which these symptoms appeared. It is, therefore, reasonable to conclude that in any case of locomotor ataxia in which the symptoms develop, we have to deal with a posterior sclerosis which is complicated by a peripheral neuritis. And here again the distinction has a bearing upon the prognosis, for the symptoms of the accidental kind may pass off, while those due to the central lesion will remain. While these conclusions of the French authors are of importance, it must be noticed that their claim that trophic disturbances are due to a complicating neuritis is by no means substantiated by the history of cases of multiple neuritis, in which, as we have seen, trophic disturbances of the varieties mentioned do not occur.

*Prognosis.*—The prognosis in multiple neuritis is good, provided the exciting cause can be removed. The only cases which form an exception to the rule are those whose constitution is much impaired by excesses or by other diseases.

*Treatment.*—The treatment of multiple neuritis requires patience, but receives the reward of success. As we have already seen, the majority of the patients recover, and it is probable that, if the cause of the affection were removed and the patients placed in favorable circumstances, expectant treatment would alone be sufficient. It is, however, not advisable to let therapeutics play a passive part. The course of the disease can be altered and its duration much shortened by active interference. In the stage of invasion the free use of salicin, salicylic acid, or the salicylate of soda, seems to have important results. These remedies cannot be said to act as promptly as in cases of acute articular rheumatism, but the consensus of opinion is that their effect in multiple neuritis is very marked. They should be given, as in acute rheumatic fever, in large doses, until noticeable effects are obtained. They should be combined with the bromide of potash or soda, partly because these drugs counteract unfavorable symptoms produced by the salicin compounds, and partly because, in the hyperæsthetic irritable condition attendant upon the invasion of the disease, they are indicated. This condition may require stronger sedatives, and not infrequently morphine must be employed to give relief from the excruciating pains. The pains are often relieved by hot or cold applications to the limbs; but as the muscles are often exceedingly tender, ordinary applications cannot be made. It is then advisable to use evaporating lotions, preferably those containing chloroform, which may be soaked into light cambric or gauze, and gently placed upon the limbs, which lie upon the softest pillows, or which may be more comfortable if the patient is put upon a water-bed. Applications of a five per cent. solution of carbolic acid have also been of use. If cool applications prove intolerable, heat may be employed. The limbs may be enveloped with cotton and covered with oiled silk, a light bandage keeping these in place; or they may be frequently bathed in hot water, and hot bottles placed against them, some soft substance intervening. One of my patients found great relief from the paræsthesia by cold douches, while another preferred the use of hot water. It is best to let the patient decide, as long as the application has to be made for the relief of pain. Gentle friction with oil of coconut often affords comfort. In the chronic stage, as we shall see presently, heat is to be preferred to cold. Cases which are distinctly syphilitic, if such occur, should be treated from the outset with inunctions of mercury and large doses of iodide of potash. I believe that both these drugs should be employed together, even in the tertiary stage of syphilis, and it is my experience that all syphilitic nervous lesions, whether central or peripheral, yield more promptly to their combined use than to the employment of either alone. Malarial cases must be treated with quinine or Warburg's tincture. In non malarial cases quinine has proved of no avail. In cases which are due to poisoning of any kind the first necessity is to eliminate the toxic agent from the system, and the second to prevent any further injection of the poison. Iodide of potash aids in the elimination. The second indication is easily fulfilled when

arsenic or lead are the toxic agents; but when the case is due to chronic alcoholism special precautions are needed. Alcoholic cases require from the outset special treatment. The condition at the time of the onset of the paralysis may be one verging upon delirium tremens. If all alcohol is suddenly removed, without due care to supply some other heart-stimulant and to secure the perfect nutrition of the patient, serious collapse may ensue. The first necessity is therefore to take care of the general condition of the patient. If this will admit of the immediate withdrawal of all alcoholic stimulation, it should be done; if not, the alcoholic beverage must be immediately reduced in quantity, and as soon as possible wholly cut off. The use of milk diet, or kumyss, or pancreatized milk, or if necessary, rectal alimentation, will be followed by a gradual recovery of the power of assimilation, and as soon as the patient ceases to lose weight all alcohol may in any case be safely stopped; its elimination by the intestines and kidneys may be hastened by appropriate means, and cerebral symptoms if they arise may be treated as in other cases of alcoholic intoxication. But it is in the chronic stage, when the patient is gradually recovering, that the vigilance of the physician is called into play to prevent a renewal of the poisoning. It is amazing that patients who know perfectly the injurious effect of alcohol upon them should insist upon getting it. But it is done. And when these patients are surrounded, as is often the case, by sympathizing friends, or servile domestics, or unscrupulous nurses, who do not appreciate the importance of total abstinence either for themselves or for the patient, they often succeed in baffling all attempts to deprive them of the favorite drink. It is only when they are watched constantly by persons who can be implicitly trusted, and who have sufficient authority to cut off all surreptitious supplies, that the physician can feel sure that his commands are obeyed. And this precaution is by no means needless even when it is probable that family servants are trustworthy. For the continued pleading and remonstrance of the patients may corrupt the best of attendants, especially if accompanied by threats of discharge at a future day. It is therefore necessary to place these patients under the surveillance of trained nurses from the start, or to remove them to an institution where they are under control.

In the chronic stage the drugs which are of greatest service are strychnia and arsenic. Strychnia may be given in doses of  $\frac{1}{16}$  to  $\frac{1}{8}$  gr. t.i.d. and it is well to combine it with phosphoric acid and the syrup of the hypophosphites. Arsenic may be used in tablets or pills containing  $\frac{1}{16}$  to  $\frac{1}{8}$  gr. t.i.d. or in Fowler's solution, five to eight drops t.i.d. The use of iron with these two drugs will be indicated in the majority of cases where there is attendant anemia. In alcoholic cases both arsenic and strychnia may increase the mental irritability, but should be continued unless this becomes too great. I have seen benefit from both of these drugs, and think it well to employ them alternately, using each for about two weeks at a time.

The remedies used in the chronic stage have two objects: one is to increase the rate of repair in the nerves; the other is to keep the nutrition of the muscles as good as possible. While the drugs mentioned probably meet the first indication, there are other remedies which meet both. These are massage, warm baths and electricity. The proper manipulation

of the limb increases the circulation in it. The increase of circulation brings fresh supplies of material to the nerve which is undergoing repair; it also aids the nutrition of the muscle, which would otherwise be decidedly affected by the sluggish flow of venous blood, due to the lack of functional activity. As soon, therefore, as the active progress of the disease is checked and the muscular tenderness has sufficiently subsided to allow the limbs to be rubbed, this potent remedy should be employed daily.

Allusion has already been made to baths and douches in the early stage, for the purpose of quieting sensory symptoms. In the chronic stage the object is a different one. Like massage, warm baths and douches stimulate the circulation and aid the nutrition and reparative processes in progress. Hence they are to be used daily. And if the warm bath be given at night it will secure not only a local action, but produce a general sedative effect, insuring quiet rest. In multiple neuritis, as well as in many other nervous affections, not due to *æmia*, a warm bath at night, or a warm douche to the neck and spine, is far preferable to and more efficacious than the majority of hypnotic drugs in causing a good night's sleep.

The last agent to be mentioned is electricity. It is, however, among the first in importance, and in its use it is necessary to know what object is sought in its application. There is first the object of increasing the progress of nerve regeneration. This may be attained by the application of a constant galvanic current in the degenerated nerve, passing the current through the nerve in either direction, or in both alternately. A mild current should be employed, its strength being measured by a galvanometer. The strength of the current will depend: (a) on the size of the sponges placed upon the skin, (b) on the pressure upon the sponges, (c) on the resistance of the skin, and (d) on the number of cells of the battery used.

If the sponges are two inches in diameter, six milliamperes is enough; if they are three by five inches in measurement, twenty milliamperes should not be exceeded. If no galvanometer is used, the strength of the current employed is uncertain. But it is to be remembered that the current grows stronger the longer it passes, since the skin resistance is gradually overcome; and therefore, if the strength is measured in cells, the number of cells used should be decreased gradually during the application. As so few practitioners use a galvanometer it may be well to state that with large sponges, (that is, three by five inches) wet with warm water, a freshly-filled bichromate of potash battery will give nearly one milliamperé of strength for every cell used during the first three minutes, provided the sponges be put on any part of the body except the soles of the feet or the palms of the hands, and pressed firmly upon the skin. After the first three minutes, the body-resistance decreases, so that when twenty cells are used to start with, one should be cut off every half minute until the number is reduced one-third. The duration of the application should be about ten minutes to each limb. During this time the distal sponge should be passed over various parts, so as to include all the nerve-branches in the current; the central sponge should be put over the nerve-trunk high up on the limb. The current should be begun and stopped gradually, and never suddenly broken. Applications may be made daily.

The second object to be obtained is to re-establish the conduction of impulses in the regenerated nerve. This is secured by the method just described. It may be attained by the use of faradism, the interrupted secondary current being sent along the nerves by placing one pole over the nerve-trunk and passing the other over the skin of the limb. The strength used should be just sufficient to be felt distinctly through the palms of the operator's hands. The third object sought is to maintain the nutrition and function of the muscles by exercising them, and thus preserving their normal irritability. This cannot be done by a faradic current, as long as they do not contract to it. The galvanic current must therefore be employed. But now it is not a steady current which is needed, for this does not cause any motion. It is only when the steady current is suddenly broken and renewed, that the contraction occurs. Hence we place one pole over the trunk of the nerve, and the other upon the muscle, and with an interrupting electrode make and break the current at the pole which is on the muscle. The pole which produces a contraction with the least current possible, is the one to be applied to the muscle. This is in R.D., the positive; in normal conditions, the negative pole. Each muscle should be exercised for three or four minutes every other day. When electrical treatment is thus employed every marked improvement is observed, which can be measured accurately if a galvanometer is used, since every week will show a change of the strength of current needed to produce muscular contractions toward the normal.

The treatment must be kept up, in the chronic stage, until recovery is complete.

If contractures have occurred in the paralyzed limbs persistent massage may overcome them. If it does not, they are to be treated on general surgical principles.

#### A CASE OF CONTRACTED FINGERS (DUPUY-TREN'S CONTRACTION) SUCCESSFULLY OPERATED UPON AFTER THE METHOD OF MR. ADAMS (ILLUSTRATED).<sup>1</sup>

BY JOHN HOMANS, M.D.,  
Surgeon to the Massachusetts General Hospital.

THE patient, who is thirty-two years old, is a conductor of a railway train. The contracted and perfectly stiff condition of the third and fourth fingers of his left hand vexed and hindered him all day long in his occupation of collecting tickets and fares. This contraction had been going on for nine years, and was started by a wound of the palm, until, when he applied for relief in March, 1886, his little finger was flexed almost completely on his palm; his ring-finger was bent at a right angle, and his middle finger was somewhat bent. He was admitted to the Massachusetts General Hospital, and I agreed to operate if he would take time for after-treatment and be patient, and not be disappointed if amputation of the little finger became necessary. I need not say that he deserves commendation for having been a most satisfactory patient. Dr. S. J. Mixer, Surgeon to Out-Patients at the Hospital, took these photographs (Figs. 1 and 2)

<sup>1</sup> Read before the Surgical Section of the Suffolk District Medical Society, December 1st, 1886. Patient exhibited.

before and after treatment, and I am under great obligation to him for this service, as well as for his uniform kindness and assistance in many other ways.

FIG. 1.

FIG. 2.

Mr. Adams states that finger contraction takes place in men at about the middle, or beyond the middle period of life. He has never seen it in women. As one finger (generally the little one) becomes bent, the next one follows, and then the next adjacent, but the first finger and thumb usually escape. The pathology and treatment of this contraction are not wholly settled; but the French surgeon, Dupuytren, in 1832, first showed that the flexor tendons have nothing whatever to do with the contracted state of the fingers, and that they are not shortened an atom, but that contraction of the palmar fascia, and its prolongations, binds down the fingers with bands as stiff and unyielding as steel; and that these contracted bands of aponeuroses have only to be divided thoroughly to liberate the stiff fingers.

I will quote at length, from Mr. Adams, a description of Dupuytren's discovery and conclusion.

"A man, who for some time had been under the observation of M. Dupuytren, and was the subject of this deformity, died, and M. Dupuytren succeeded in gaining possession of the arm and hand. A careful drawing of the parts was made before dissection. The whole of the skin was removed from the palm of the hand, as well as from the palmar surface of the fingers. The result was the complete disappearance from it of the folds into which it had been gathered. This opening-out showed that its arrangement during the disease was communicated to it, but in what way, or by what means, was not evident. Continuing the dissection, the Professor exposed the palmar aponeurosis, and was surprised to find it retracted and shortened. From its inferior part were given off bands, which passed to the sides of the affected finger. On making movements of extension in the affected fingers, M. Dupuytren observed that the aponeurosis underwent a kind of stretching and crackling. This threw light on the subject. It seemed clear that the aponeurosis was somehow connected with the deformity produced by the disease. The affected point remained to be discovered. The prolongations to the sides of the fingers were then divided; the contraction disappeared at once, and the fingers assumed their normal condition of one-third flexion. The smallest force was now sufficient to bring them into a state of complete extension. The tendons were not implicated in any way, and their sheaths had not been opened. All that had been done was the removal of the skin, and the divisions of the bands of aponeurosis going to the bases of the phalanges.

"In order to remove all doubt and objections, M. Dupuytren dissected out the tendons. They retained their natural volume and mobility, as well as the smoothness of their surfaces. Continuing the examination, it was found that the articulations were in their natural condition, the bones not enlarged, roughened, or presenting in any way, either externally or internally, the smallest degree of change. No alteration was observed in the apposition of the articular surfaces, nor in their external ligaments, no ankylosis; nor had the synovial sheaths, or the cartilages, or the synovial membranes, undergone the slightest change. The conclusion naturally arrived at from these conditions was that the starting point of the disease was the excessive tension of the palmar aponeurosis. As regards the cause of the palmar lesion, it was considered to result from injury to the aponeurosis, caused by the too violent or too prolonged action of some hard body held in the palm of the hand."

This deformity has since been spoken of as "Dupuytren's finger contraction"—a well-deserved compliment to a great observer and surgeon.

I will not discuss the causes of the affection, but will describe the operation in my present case, and that will give a good idea of the usual manner of proceeding: On March 27th, 1886, after etherization, a puncture was made between the transverse crease in the skin and the annular ligament (as advised by Mr. Adams) with a very fine tenotomy knife. This puncture should be made where the skin is not adherent to the fascia nor tightly stretched, so that the knife can be readily introduced between the two. I then cut downwards, dividing the tight bands and any digital prolongations that I could find. I then made a second puncture as near the finger as possible, and divided bands in the same way. Other punctures and divisions were then made between these two. All this cutting was done as subcutaneously as possible. The punctures were covered with carbolyzed absorbent cotton, and the fingers immediately straightened as much as possible, and bound to a moulded metallic splint. This immediate extension is a most important part of the treatment. Pain was relieved by morphia. On the 28th the fingers were somewhat swollen; on the 30th he was up and about. The extension was increased on the 31st, and the little finger was much straighter, and the ring-finger nearly straight. After this he was treated as an out-patient. Here are some illustrations from Mr. Adams's book, showing that the tendons are not all involved, as they may be seen lying against the phalanges and in their sheaths, while the cause of the contraction (the fibrous bands of aponeurotic tissue) are well shown.

Mr. Adams goes on to say:

"Anatomical impossibility of the flexor tendons being involved in contraction; the impossibility of the flexor tendons being involved in Dupuytren's contraction of the fingers, will, I think, become apparent to any surgeon after an attentive examination of the anatomical relations of the flexor tendons to the fascia and the bones at the parts where the most prominent contracted cords usually exist, namely, first, in the palm of the hand, at a spot corresponding to the transverse flexion furrow, where the most tense and prominent solitary cord generally exists; and, secondly, in the neighborhood of the cutaneous web between the fingers, where the smaller, but very resisting contracted bands of fascia are always met

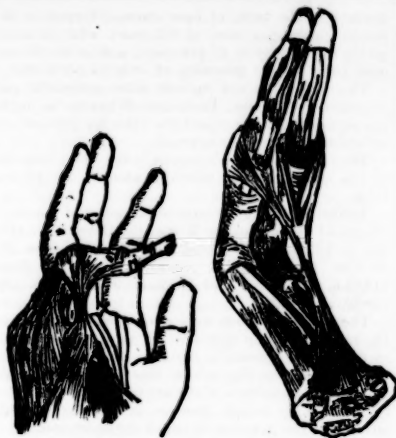

FIG. 3.

FIG. 4.

No. 4. Contraction of palmar fascia. (After Adams.)

with, and are directed towards the sides of the phalanges. At these two spots we have then particularly to study the anatomical relations of the flexor tendons to the fascia, and to the bones.

"First, with regard to the transverse flexion-furrow in the palm of the hand: by this, I mean a transverse crease which, on flexion of the fingers, is converted into a deep furrow, passing transversely across the palm of the hand, rather more than an inch above the margin of the cutaneous web between the fingers. This transverse crease or furrow is no doubt produced by the habitual flexion of the fingers upon the palm of the hand, and will be found to be more conspicuous in proportion to the hand-labor performed. This transverse crease, or flexion-furrow, precisely corresponds to the metacarpo-phalangeal articulations, and if a needle is entered at this transverse furrow on the palmar aspect, it will, in transfixing the hand, pass through the metacarpo-phalangeal articulation.

"Now, we know, as an anatomical fact, that the flexor tendons of the fingers enter into a dense tubular sheath on the palmar aspect of the first phalanx, just at the margin of the metacarpo-phalangeal articulation, and continue their course along the finger, in close proximity with the bone, so that a needle transfixing the hand from the transverse flexion-furrow in the palm, very closely indicates the spot at which the flexor tendons enter their dense tubular sheath. From this dense tubular sheath no anatomist would believe the flexor tendons could be dislodged by any traction power exerted by contraction of the palmar fascia; yet the spot at which the tendons enter the sheath, also corresponds to the most prominent part of the large solitary contracted cord, observed in the palm of the hand.

"Reasoning, therefore, from these anatomical facts, we can only conclude that the tense solitary cord in the palm of the hand must be one of the four large sub-divisions of the palmar fascia, into which it

divides, and which pass towards the four outer fingers, as far as the metacarpo-phalangeal articulations; and it is therefore impossible that the flexor tendons of the fingers could be reached or divided by the surgeon when he divides the tense solitary cord in the palm of the hand.

"Secondly, opposite the metacarpo-phalangeal articulations, the four great sub-divisions of the palmar fascia are connected by transverse bands, and then they subdivide into digital prolongations, which pass on either side of each finger towards their insertion into the bone of the first phalanx, external to, and along the margins of the dense tubular sheath enclosing the flexor tendons.

"The insertion of the digital prolongations of the fascia into the periosteum of the first phalanx, is not accurately described in many anatomical works—the insertion into the sheaths of the tendons being more generally recognized. Professor Curnow, of King's College, is in the habit of directing the attention of his class especially to the insertion of the digital prolongations of the palmar fascia into the periosteum of the first phalanx, external to and along the borders of the sheath of the flexor tendons.

"I have satisfied myself of the accuracy of this by my own dissection, and have seen it admirably displayed in the dissections used by Dr. Curnow.

"It appears to me that the drawing down of the first phalanx is the more readily explained when the insertion of the digital prolongations of the fascia into the periosteum is borne in mind.

"It will thus be seen that above and below the transverse flexion-furrow in the palm of the hand, we have important differences in the anatomical arrangement of the palmar fascia; above this line, we have the four great sub-divisions of the palmar fascia, proceeding centrally towards the four outer fingers; and below the line towards the fingers we have the digital prolongations of the fascia proceeding laterally to the sides of the phalanges.

"The tense solitary cord frequently seen above the transverse flexion-furrow might well, from its situation, direction, and thickness, be taken for one of the flexor tendons; and in my earlier operations I divided it in the belief that it was a tendon, or at least that the tendon and its sheath, as well as the palmar fascia, were involved in and contributed to form the tense contracted cord. The after-treatment, by gradual mechanical extension, was also based upon this supposition, which I have now satisfactorily proved to have been erroneous. It was the conviction of this error which led me to abandon the method of gradual mechanical extension, and adopt the plan of immediate extension advocated in the present paper."

I have thought this case interesting enough to bring before this Society, and to call attention to the successful treatment of this very annoying disease.<sup>2</sup>

After a cure has taken place, it is well for the patient to wear some form of light retentive splint at night.

— The present value of the Johns Hopkins endowment is said to be about \$5,000,000. It yielded a net income, last year, of about \$226,000.

<sup>2</sup> For further information on this most interesting subject, the reader is referred to "Observations on contraction of the fingers and its successful treatment by subcutaneous divisions of the palmar fascia and immediate extension," by William Adams, F.R.C.S. London, J. & A. Churchill, 1879.

SUBPERIOSTEAL AMPUTATION AT THE HIP-JOINT AFTER HIP DISEASE.<sup>1</sup>

BY E. H. BRADFORD, M.D.

NEGLECTED cases of hip-joint disease occasionally present themselves, in which, owing to extensive caries of the pelvis or in the length of the femur, excision offers no chance for a cure; in other instances excision has failed to arrest the destructive process in the bone, and the surgeon is left to choose between surrendering the patient to a lingering and wretched death, or the very radical measure of amputation at the hip-joint.

In making this choice he needs information as to the chances of recovery offered by amputation, and if the operation is decided on, as to the best method of procedure.

The former can not be found in the ordinary tables of mortality after amputation, as it would appear that the risk of death is greater when this operation is done after injury, or for the removal of tumors, than when the patient is freed by the amputation from an extensively carious and useless limb, which has itself served as an impediment to recovery.

Ashhurst<sup>2</sup> has collected thirty-four cases of primary amputation at the hip-joint for hip disease, and thirty-one consecutive, (that is, after excision,) and found nineteen deaths. This, rejecting five cases where the result was undetermined, would give a mortality of thirty-two per cent.<sup>3</sup>

The death-rate of amputation at the hip-joint after injury is 70.9 per cent., and for disease in general, 42.6 per cent.

It is to be expected that this percentage of mortality may be reduced by greater attention to detail, as in the case with other large operations. In fact, an examination of the accompanying table of cases of hip amputation (after hip disease) done since Ashhurst's table was made, would substantiate this idea. This is the more noticeable as important improvements in controlling hemorrhage have lately come into vogue in the operation.

According to Ashhurst, we have 60 cases, with 19

<sup>1</sup> Read at the meeting of the Surgical Section of the Suffolk District Medical Society, held December 1st, 1886.

<sup>2</sup> International Encyclopedia of Surgery, Vol. iv, page 501.

<sup>3</sup> One of these nineteen fatal cases (that of Buffon) should strictly be considered an operative success, as death did not take place till three months after the operation.

deaths; in the table of later cases, 22 cases, with 3 deaths; making a total of 82 cases, with 22 deaths, giving a mortality of 27 per cent., and in the 22 cases done since 1880, a mortality of only 14 per cent.

This table does not include other successful cases reported by Denons, Buchanan Wheaton, as it was not certain from the report that the hip-joint was involved in the caries or necrosis.

The mutilation which results is the chief objection to the operation, but partially met by an artificial limb.

Artificial limbs have been reported as of use in the "Surgical History of the War of the Rebellion," (Part III, p. 131); and by Denons, *Bulletin and Mem. Soc. de Clin.* (xxxvii, 560.); Shuter, *Clin. Soc. Trans.* (1882-3, xvi, 86); and Barker, *Trans. Clin. Soc.* (1882, xvi, 258).

The two latter cases were done subperiosteally, and the resulting stump appeared to show a new bone or cartilaginous formation, in the periosteum of the femur left in the flap, which was of material assistance in the usefulness of the artificial limb. Shuter's case should be looked upon as illustrating a decided advance in the practical value of the operation.

An undoubted reformation of bone has taken place in the case operated upon by the writer three years ago. As yet no artificial limb has been fitted, as the patient is still young — ten years of age.

At the time of operation he was reduced to lowest limit of emaciation; excision of the hip had been done with but temporary benefit, and there was extensive disease of the pelvis and pelvic abscesses. He has steadily gained since the operation; several sinuses remained in the flap which was riddled before the amputation. A few abscesses have appeared in the stump from caries of the pelvis. These have, how-

ever, all healed with the exception of one, which has nearly healed. The boy has increased in weight, and now is heavier than boys of his age (ten years), weighing fifty-six pounds. According to Bowditch's tables, a boy of that age should weigh sixty-four pounds. He is fifty inches tall, which should give in the average boy a weight of sixty pounds. Considering that he has lost one entire lower extremity, which may be estimated as weighing at least ten pounds, it will be seen that he is above the standard in weight, an evidence that the carious process is arrested in progress.

Absolute economy of blood — of the utmost importance in all hip amputation — is vital in cases reduced to the physical extremity seen in cases of hip disease undergoing this operation.

For controlling hemorrhage neither digital compression nor abdominal tourniquets are to be trusted, although the former can be used in children with less risk than in adults, and is still used by Marshall. Davy's lever in the rectum has caused death by perforation of the gut, and has little but novelty in its favor.<sup>4</sup> Trendelenburg's method of compressing the flaps by means of a rubber tube which is placed over the thigh and is wound round both ends of a steel rod passed through the thigh, the vessels being compressed between the rod and the rubber tube, presents no advantages over an elastic compression properly applied. The best way is that described by Mr. Jordan Lloyd.<sup>5</sup>

The limb should be elevated and stripped of blood, and an elastic bandage is doubled and passed between the thighs,<sup>6</sup> its centre lying between the tuber ischii of the side to be operated upon and the anus. A pad in the shape of a rolled bandage is tied over the external iliac artery, the ends of the rubber are drawn tightly upwards and outwards (one in front and one behind) to a point above the centre of the iliac crest of the same side. The front part of the band passes across the compress, the back part runs across the great sciatic notch and prevents bleeding from the branches of the internal iliac. The ends of the bandage are tightened, and should be held by the hand of an assistant placed just above the centre of the iliac crest. Mr. Lloyd suggests that a short piece of wooden rod can be slipped under the elastic, and is a convenience in holding this rubber band. This elastic bandage should not be allowed to slip down below the iliac crest or over the tuber ischii. This can be done by the hand of an assistant or by passing a bandage under the elastic and tying it to the patient's shoulder.

The method of disarticulating, so popular in the operating classes, and known as Lisfranc's method, is not readily done if an elastic tourniquet is used. To check all bleeding it will be found most convenient to amputate as if at the upper part of the thigh, and tie all bleeding points, removing the remaining fragment by a lateral incision. This is practically the method recommended by M. Furneaux Jordan. A lateral incision is made as in excision of the head of the femur — the head of the femur is excised in order that it be out of the way, the lateral incision is prolonged and the shaft of the femur separated for two or three inches in its length from the surrounding muscles — taking care that the periosteum remain with the muscles. A cir-

cular amputation of the thigh is then done, the bone sawn through, or if entirely freed from the surrounding tissues by the lateral incision, pulled out from the flaps. The vessels are tied and the tourniquet removed.

The operation in this way can be done without the loss of any appreciable amount of blood. There is time for due deliberation, as there is no danger of a death upon the table by a sudden gush of hemorrhage.

The following conclusions would appear to be justified: amputation at the hip-joint, in hip disease, should be regarded as the very last resort, contra-indicated by extensive amyloid degeneration of the viscera, or a moribund condition of the patient.

The chances of mortality are not greater than the chances given in amputation of the thigh in general.

The chances of a permanent cure (barring the mutilation) would appear to be greater than after excision at the hip-joint.

The amputation should be done subperiosteally whenever it is possible. An elastic tourniquet gives the best means of preventing hemorrhage.

Preliminary excision of the head of the femur, in freeing the upper part of the shaft, will be found to facilitate the amputation.

NOTE. — We have examined the stump of the patient shown by Dr. E. H. Bradford, at the meeting of the Surgical Section of the Suffolk District Medical Society, on December 1st, 1886, and upon whom he had three years before performed subperiosteal amputation at the hip-joint after suppurative hip disease; and we found in the centre of the stump a hard resistant mass, having on palpation the characteristics of bone. This mass was about two inches thick and four or five inches long, and projected downwards slightly flexed in the natural axis of the limb.

GEORGE H. MONKS, M.D., Secretary.

J. COLLINS WARREN, M.D., Chairman.

#### A REPORT OF FOUR CASES OF EXCISION OF THE HIP PERFORMED IN 1882.<sup>1</sup>

BY ROYAL WHITMAN, M.D.,  
Orthopedic Surgeon to the Boston Dispensary.

HAVING an opportunity to show what may be considered a successful result after excision of the hip, it was thought that a presentation of the results in three other cases, performed at about the same time, might prove instructive.

These four excisions were performed at the Boston City Hospital during my service as Intern. At that time, being interested in the comparative merits of the operation, I was surprised to find how difficult it was, in this vicinity, at least, to discover patients on whom the operation had been performed, or even to obtain any definite information from surgeons who had performed the operation, as to whether it had proved successful or otherwise. This fact has induced me to report these final results in this little group of four cases, comprising my personal experience with the operation.

CASE I. A boy, four years of age, entered the Hospital February 17, 1882, with a history of pain in the right hip, and slowly-increasing lameness of six months' duration. Examination showed muscular spasm, limitation of motion, tilting of the pelvis, pain and grating on movement of the right hip, and a fluctuating swelling, extending from the great trochanter

<sup>4</sup> Brit. Med. and Surg. Journal, September 13, 1885.

<sup>5</sup> Lancet, May 26, 1883.

<sup>6</sup> The writer has used large rubber tubing in preference to the rubber band described by Mr. Lloyd. If pulled tight the pad is not necessary. It has also proved convenient to use the tubing long enough that the ends may be brought (after the tubing is fastened on the affected side) to the well side and then fastened.

<sup>1</sup> Read at a meeting of the Surgical Section of the Suffolk District Medical Society, held December 1st, 1886.

to the middle of the thigh. The child was placed in bed, and a double T-splint, with extension, applied. This treatment relieved the pain, but as no improvement followed, on March 10th Dr. W. H. Thorndike excised the hip. Considerable pus was evacuated, and the head of the bone, which was softened and eroded, was removed just below the great trochanter. The acetabulum was not diseased. The wound was dressed antiseptically, the patient placed upon a frame, extension and fixation of the limb applied, and an immediate improvement in general condition followed. Two months later the wound had closed, with the exception of two small sinuses leading down to the acetabulum.

On June 3d symptoms of an acute attack appeared, consisting of headache, constipation, vomiting, slow pulse, and stupor, followed by coma, dilated pupils, and convulsions, with death four days later. No examination was allowed, but, from the symptoms, a diagnosis of tubercular meningitis was made.

CASE II. The patient, a boy ten years of age, entered the Hospital February 18, 1882, with a history of slight lameness of the left leg, and stiffness in the hip-joint for more than a year, with, during the past three months, increasing pain and swelling of the leg. Examination showed the left leg flexed upon the abdomen, much limitation of motion, grating in the joint, and a large, fluctuating swelling, extending from the trochanter to the middle of the outer aspect of the thigh. Under ether, the leg was extended, and a T-splint and extension applied. The abscess, however, slowly increased in size, and two weeks later a spontaneous opening formed. The patient now grew rapidly worse, and on March 4th Dr. Thorndike excised the head of the femur, just below the great trochanter. This was found to be extensively diseased, as was the acetabulum, the greater part of which was also removed. The patient died thirty-six hours later, apparently from shock.

CASE III. A boy, seven years of age, entered the Hospital January 14, 1882, with a history of a fall three weeks before, followed by pain in the left hip and knee. It is probable, however, that the symptoms in this case were of much longer duration.

Examination showed the leg flexed upon the abdomen, pain on motion, and muscular spasm. Under ether, the leg was extended, a double T-splint, with extension, applied. This treatment relieved the pain, but two months later an ovoid, fluctuating swelling appeared on the groin, which slowly increased in size. This was incised, and the joint found to be so extensively diseased that an excision was deemed advisable. On June 13th Dr. C. D. Homans performed the operation, removing the head of the bone above the great trochanter. The after-treatment was similar to that of the preceding cases.

An immediate improvement in the general condition of the patient followed; five months later the wound had nearly closed, there was but slight discharge from two small sinuses, the patient up and about on high shoe and crutches, with a moderate amount of motion in the joint. One month later he was discharged. Six months afterwards I saw him. He was then walking about on crutches; the leg was firmly ankylosed, and from one and one-half to two inches shorter than the other. There was also considerable suppuration from two sinuses leading down to the acetabulum. The boy's surroundings were very bad, and his general

condition poor. In July, 1884, two years after the operation, he died. The resident physician at the New England Hospital, where the patient remained for a few weeks during the latter part of the time, informs me that there was then a large, fluctuating tumor over the lower part of the back, a freely-discharging sinus over the site of the former operation, and that the urine showed evidence of disease. His mother says that shortly before his death "he was all swelled up." I, therefore, infer the cause of death to have been exhaustion from long-continued suppuration, with amyloid degeneration of the internal organs.

CASE IV. The patient, a boy four years of age, first entered the Hospital October 4, 1878, with a history of a fall six months before, which was followed by gradually-increasing pain and disability. Examination showed well-marked disease of the right hip. He was treated by rest and extension, and he left the Hospital six months later, wearing a Sayre's short splint. October 20, 1880, he was admitted to the Hospital, the symptoms being about the same as before, and remained two months.

On October 11, 1881, he again entered the Hospital, with a history of injury, followed by acute symptoms. The leg was found to be flexed almost at right angles to the body. This was extended under ether, and after three months of rest in bed, with extension, he was discharged on crutches, wearing a high shoe.

On January 31, 1882, he entered the Hospital for the fourth time, with the usual history. Examination showed pain on motion, moderate flexion and fixation of the joint, with a hard, elastic, semi-fluctuating swelling in the groin. A T-splint, with extension, was applied, but as there had been no improvement at the end of three months, Dr. Homans decided to excise the hip. This was done on April 10th, 1882. The head of the bone was removed two inches below the great trochanter, and the acetabulum, which was roughened, was thoroughly scraped. Careful general and special treatment resulted in closure of the wound, and the patient was discharged February 5, 1883, well, and has since remained in perfect health.

Thus, of these four patients the first died of tubercular meningitis; possibly the operation might have increased the danger of tuberculous infection, but of this it is impossible to say.

The second died from shock, though in this case the disease was so extensive and the condition of the patient so bad that probably the operation simply hastened his death by a few months.

The third died from the effect of long-continued suppuration. The operation was a failure, but it is improbable that death was hastened by it.

The fourth I show. The leg on the operated side is considerably smaller than the other. There is three and one-half inches shortening, and almost complete ankylosis, the limb being held in a position slightly adducted and flexed. This might be remedied, by making the leg slightly longer, but the patient objects to further interference. With a high shoe he walks long distances without especial fatigue and without artificial support, though with a decided limp.

This result would not be considered a brilliant one by those who expect free motion after every case of excision; but practically, if the two periods of four years before and after the operation be compared, the first of more or less pain and disability, interspersed with fifteen months' confinement in a hospital, and

the second of continuous good health, the operation may, I think, in this case be classed as a success.

In regard to the merits of the operation itself, the weight of surgical opinion in view of the very satisfactory results obtained by careful and continued conservative treatment, is that the operation should be limited to those cases in which it is either impossible to carry out such treatment, or where conservative treatment carefully carried out is unavailing. In other words, to consider excision of the hip as a life-saving operation. If then, the operation is, as a rule, to be reserved to those cases where conservative treatment has failed—cases of extensive destruction of bone and soft parts, in such cases any hope of preserving useful motion in such joints should be discarded, and the operation conducted in the hope of relieving the patient, exhausted by pain and long-continued suppuration, as speedily as possible.<sup>1</sup>

A large incision should be made and the bone removed well down below the trochanter; all the diseased soft parts, including the periosteum, and the capsule, should be removed, all sinuses thoroughly scraped; the extremity of the femur placed as nearly as possible in apposition with the acetabulum, the soft parts united by deep sutures placed in layers to close the cavity and prevent retention of secretions, the limb placed on an immovable apparatus; dry non-irritating antiseptic dressings, preferably in connection with iodoform, applied, thus hoping to secure rapid closure of the wound and ankylosis. But, as in these cases of long standing it can scarcely be hoped to remove, at the first operation, all action or latent disease, if healing does not result, the suppurating wound should again and again be explored in the hope of final success. The ordinary procedure is, or has been, to treat both recent and advanced cases alike, simply removing the head of the femur through a small incision, leaving the periosteum with the attached muscles in the hope of obtaining a movable joint. If healing does not result, nothing more is attempted. I think this point has not been sufficiently insisted upon: that the operation having been undertaken with the object of relieving patients from the danger of a chronic exhausting disease, they should not be sent back to their wretched homes with unhealed suppurating wounds; but if persistent attempts to effect a cure by excision have failed, amputation should be undertaken as a last resort.

—Sergeant Boston Corbett, the man who shot J. Wilkes Booth, has become insane. His maniacal outbreak was characterized by his arming himself with a pair of revolvers, and dispersing the officers, and finally, the members of the Kansas Legislature, which body he served in the capacity of assistant-door-keeper.

<sup>1</sup>De la Coxalgie, par le Prof. Ollier. Congrès français de Chirurgie, 1885.

<sup>2</sup>As my experience increases and the longer I watch patients on whom I have performed the operation of excision of the hip, the less I am satisfied with movable joints. There are, of course, advantages in being able to bend the thigh and seat one's self, but it is of much greater importance to be able to walk all day, not to be protected from the danger of recurrence of disease by a good heavy union. In those who preserve movable joints, the extremity of the femur is generally loosely attached, it always slips up more or less on the pelvis or rather the pelvis slips down on it, the weight of the body stretching the fibrous bands so that the pelvis is as it were suspended on the femur. We must consider not the immediate but the final results; and I repeat among my patients who work at laborious occupations, those whose femurs are ankylosed with the pelvis, are much better satisfied than those who preserve movable joints.<sup>2</sup>

## REPORT ON MENTAL DISEASE.

BY HENRY R. STEEDMAN, M.D.

### EPILEPSY WITHOUT UNCONSCIOUSNESS.

BALL,<sup>1</sup> in introducing a carefully-observed case of true epilepsy without unconsciousness, criticises as too absolute the definition of that malady which makes unconsciousness a necessary accompaniment of all attacks, and contends that this accepted formula, like all absolute rules, has its exceptions. Somnambulism, for example, is nearly always attended by obliteration of consciousness during the sleep-walking stage, but it is equally certain that some sleep-walkers do retain the recollection of what has happened during that interval; so it is with epilepsy. In the immense majority of cases consciousness is abolished during the attack, but in a very few exceptional instances this is not so. A case reported by Major is quoted by Bucknill and Tuke, and several similar cases have been met with by others. The medico-legal importance of such cases is readily appreciated. A man commits a crime while in the epileptic state, and is held to be irresponsible; but if we admit the accepted definition of epilepsy, he cannot be considered an epileptic if he retains the slightest recollection of what has happened during the attack.

The case in point is that of a married woman of thirty-two years. Her father, an habitual drunkard, died at the age of fifty-two. Several brothers and sisters died, when young, of convulsions. The patient began to have convulsions for a time when seven years old, and soon after her marriage, at the age of twenty-three, during pregnancy, she had attacks of an epileptiform nature. For seven years afterwards, during which time she has been under Dr. Ball's observation, she has had seizures, at variable intervals, of three different kinds. First, she has, but very rarely, genuine epileptic convulsions (grand mal), ushered in by a cry, facial pallor, etc., and attended by foaming at the mouth, and the characteristic convulsive movements of all the limbs of the tonic and clonic type. One of these attacks was witnessed by Dr. Ball. Somewhat oftener she has attacks of epileptic vertigo, "absences," of short duration (petit mal). But by far the most frequent seizures are characterized by delirious excitement. She gives a scream, turns pale, and cries out, "Oh! God leave me!" jumps out of bed, and runs about the room, indulging in all sorts of absurd conduct, and sometimes even violently attacking others. It is only in attacks of the last variety that she retains recollection of what has happened, and it has only been during the past year that this peculiarity has been manifested.

In one of these seizures (November 25, 1885) she said to her husband, "I am going to bite you," and then, putting her threat into execution, she bit him and spat in his face. On coming to herself, she remembered the occurrence perfectly, and said to him, "Didn't I say I was going to bite you, and didn't I really do so, and spit in your face?"

In another of these attacks, which occurred at night, she left her bed and went to her ironing-table. She also tried to find her needles, thread, and the rest of her sewing implements. The next morning, on awaking, she remembered this circumstance very clearly,

<sup>1</sup>L'Encephale for July and August, 1886.

<sup>2</sup>The Neurological Review for November, 1886.

and told her mother of it, who expressed surprise at this unexpected return of her memory.

On January 11th, 1886, in the midst of an attack, she seized an ink-stand and threw it at her mother's head. Several minutes later, when the attack had passed, she recalled the whole affair unaided, and could not apologize enough for what she had done. Her memory returns in this way, but seldom, however, and in the immense majority of her seizures; all recollection of what has passed is completely effaced.

Such instances as these seem to show conclusively that amnesia is not a distinctive mark of epilepsy. In fact, it is very probable that if attention were generally directed to this point, the number of reported cases of the kind would be greatly augmented.

Bannister,<sup>2</sup> in a recent article on "Consciousness in Epilepsy," treats the subject quite exhaustively, and comes to the following conclusions:

(1) That the epileptic discharge may, in rare instances, take place in motor regions of the cerebrum, and not involve at all, or to any extent, those parts concerned in psychic functions so far as to seriously affect or abolish consciousness, meaning by that term a vivid sense of being and knowledge of one's thoughts and actions, continuous with that in the normal condition.

(2) That in the so-called automatic epileptic conditions there may be a state of double consciousness, as it may be termed, in which it cannot always be said that the mental functions in the abnormal condition is less perfect and complete than in the normal state.

(3) The post or pre-epileptic outbreaks of violence, the so-called epileptic mania, are not necessarily attended with loss of consciousness, but may be, in some cases, simply manifestations of extreme morbid bodily and mental irritability, with loss of self-control, but with no more impairment of consciousness than might be caused by similar emotional disturbance under other conditions.

(4) That there may be a true automatism in epileptics, not attended with any apparent loss of consciousness, and due, possibly, to the rapidity of some psychic reflexes exceeding the limits of the reaction time necessary for their conscious recognition.

(5) That the definition of epilepsy which makes loss of consciousness an essential character, is an arbitrary one, not supported on pathological or clinical grounds, either in the ordinary convulsive phase of the disease, or in its psychic manifestations.

#### CRANIAL EXAMINATIONS IN THE INSANE.

M. Verga,<sup>3</sup> a prominent Italian authority on insanity, thinks that, in the present state of our knowledge, little is to be gained by examining the crania of the insane. We may, to be sure, feel through the scalp certain coarse lesions of the skull of more or less recent origin, projections, depressions, and exostoses, which may possibly reveal the traumatic or syphilitic nature of the mental impairment, but that is all. Lasegue's views of the relation between epilepsy and plagiocephalus and corresponding facial asymmetry are often contradictory to facts. M. Luy's opinions regarding a cranial prominence corresponding to the paracentral lobule are far from being proved. The indications found by measurements of the skull are only of value in extreme cases. The assistance to

be gained by cranial percussion, auscultation, and thermometry, he finds to be next to nothing.

#### PARANOIA.

Kierman<sup>4</sup> quotes Spitzka's graphic description of monomania, and notes his abandonment of this term for that of paranoia. The latter was introduced by Heinrich, and first applied to this class of cases by Kahlbaum, and is now in use in Italy, Germany and the United States. It has been variously designated imbecility of the first grade, *mania systematisée*, *pazzia sistematizzata primitiva*, *megomania*, *vesania*, *wahnsinn*, chronic mania, insane temperament (congenital type), *folie héréditaire* (hereditary type), primary monomania, primary paranoia, dementia monomania, *primäre Verrücktheit*, monomania, protopathic insanity and *primärforygethet*. Several cases of paranoia are reported by the writer, and all answer to the description of chronic delusional mania of some English and American authors. He considers this psychosis likely to contribute a considerable part to the insane population, both directly and by its victim leaving descendants. About ten per cent. of the population admitted to the German and Italian insane hospitals are victims of this psychosis, while about seven per cent. of the resident population are also paranoiacs. In American asylums one-third of the 921 tabulated were Americans. These furnished 49 paranoiacs. The remaining 606 furnished 99 paranoiacs, or more than double the proportion of the paranoiacs resident in German and Italian asylums. From these and further researches conclusions are reached as follows:

*First:* The character of the government and institutions of the United States is such as to attract thither the paranoiacs, since they are fertile project-makers, and see in the United States a great field for all such projects.

*Second:* In consequence of the peculiarly unsettled condition of civilization in many parts of the United States, these paranoiacs readily pass muster, even become leaders in the community, and often rear families, their insanity never being discovered.

*Third:* In all probability at least one-seventh of the insane entering the United States are paranoiacs, whose insanity is so sufficiently concealed as to enable them to pass as sane until long after their arrival: to marry and leave a neurotic inheritance to their descendants.

*Finally:* Until the ancestry and history of immigrants into the United States is rigidly traced, and the insane excluded, insanity will increase among the foreign-born population of the United States and their immediate descendants in a disproportionate ratio.

#### GRANULATIONS OF THE EPENDYMA OF THE VENTRICLES OF THE BRAIN.

Brunet<sup>5</sup> notes the fact that these granulations are more abundant by far upon the lateral portions of the antero-inferior wall of the fourth ventricle than elsewhere. All authors attach the greatest importance to the granulations of the fourth ventricle because of the physiological functions of the medulla oblongata, and their presence in this ventricle is one of the chief reasons given for considering general paralysis as a periencephalitis rather than a pericerebritis.

Lays, although far from agreeing that this lesion is peculiar to general paralysis, has only very rarely

<sup>2</sup> Archives Italienne per le Malatie Nervose, March, 1886; and L'Eucéphale for September and October, 1886.

<sup>4</sup>The Neurological Review, Vol. 1, No. 1. May, 1886.

<sup>5</sup> Annales Psychologiques, March, 1886.

encountered it in any other disorder. Magnan and Mercejewski, who have made a special study of these granulations of the ependyma of the ventricles of the brain, consider them the most important lesions of general paralysis. Brunet, however, believes that their importance has been greatly overestimated, especially as regards the granulations of the fourth ventricle. He has often found them present in disorders other than general paralysis, and in that disease itself they are by no means constant appearances. They are found in nearly every form of mental disorder, while they are usually absent in rapid cases of general paralysis in which the pia mater, although very adherent to the cortex, is somewhat thickened and the convolutions have not had time to become appreciably atrophied. They are well-marked in hydrocephalus, chronic mania of long duration with dementia, and in epileptic dementia. Speaking generally, we may say that they bear a certain relation to thickening and opalescence of the pia and arachnoid and to atrophy of brain and sub-arachnoid and intra-ventricular effusion. If they are more numerous and prominent in general paralysis, it is because in that disease, more generally than in any other, are combined these three changes. Plaxton's view, that these granulations are post-mortem changes, is also worthy of consideration. The writer concludes that as: 1st. These granulations are neither constant in, nor peculiar to, general paralysis; 2d. Sclerosis of the parts composing the isthmus of the encephalon, is only an accidental and terminal lesion of that affection; 3d. The cerebellum is intact, as M. Baillayn has just shown, and as the writer himself has observed—that therefore the name *pericerebritis* is better adapted to general paralysis than that of *periencephalitis*.

#### THE USE OF SEDATIVES IN INSANITY.

Writing of the use of sedatives in insanity, Dr. Savage\* says that though asylum physicians erred very naturally in using them occasionally as restraints, but more freely as means of control, the general practitioner has done so much more, and will continue so to act and err so long as public feeling is so strong against asylum treatment. He protests against the use of these drugs as a rule. The patients at Bethlehem (where recent cases are treated almost exclusively), are treated almost without the use of the common sedatives—bromides and morphine, chloral and opium, being very rarely used indeed. The treatment by drugs differs according as the patient has organic or functional brain disorder. In general paralytics severe measures may be rapidly destructive. The early and excited general paralytic is very often easily affected by alcohol, so that a glass of wine will often make such a one appear to be drunk; and in the same way a slight opiate or a small dose of hyoscyamine may produce serious effects. In advanced senile atrophy the same effects are observed. In true brain decay, it is better to avoid any of the stronger sedatives, and rather to use small and repeated doses of the milder ones. As in the latter cases one must be careful not to begin with too large doses, so in functional mental disorders we must sometimes not be afraid to give large doses.

Bromide of potassium is seldom given alone in cases of insanity, and it is rare to find a violent case of mania benefitted by the use of this drug or by chloral

or by their combined employment. As to chloral, Dr. Savage finds it hard to be just, as he has seen so many disastrous results from its abuse that it is to be feared that more harm than good has followed its introduction. It is the first thing now taken by the man of intellect who is overworking, and is eagerly sought by the nervous, fashionable lady; it is a temporary prop to the drunkard, and to the doctor in many cases it is the means of keeping a troublesome patient quiet. The chief objection to it is that it soon establishes a habit and almost always disturbs digestion. Patients are constantly admitted to Bethlehem who at once call for their night draught. It is withheld, and after perhaps three terrible days of suffering, sleep comes, and with it the delusions which have been almost embalmed by the chloral, slowly disappear. Delusions of months may thus vanish in a week. Though there is danger, aid too may be got from it; and though not trusting it fully, Dr. Savage thinks it will often prevent death in cases of acute delirious mania, if given with abundance of food and stimulants. It is also of great service in cases of epileptic furor.

#### THE "INCREASE" OF INSANITY.

Dr. D. Hack Tuke, in an elaborate statistical study on alleged increase of insanity, dwells upon the importance of ascertaining, as the only sound test of such increase, the number of *occurring* cases of mental disorder in proportion to the population during the periods of time we desire to compare. Among a number of interesting results, he finds that *so far as statistics teach us anything*, they fail to show the slightest increase in occurring insanity in England and Wales since January, 1878, when we apply the above and only reliable test. In fact, the tendency has been, on the whole, as shown in one of his tables, toward a decrease in the admissions to asylums, of patients laboring under first attacks. The question therefore arises whether the present age may not wage successful war against the causes of insanity in one direction, but at the same time favor their growth in another? Take, for instance, general paralysis. It does not admit of reasonable doubt that it has increased of late years, after abundant allowance is made for its better recognition; but if the frequency of insanity, as a whole, has undergone little change, it would look as if some form of insanity other than general paralysis, had declined. Dr. Tuke also thinks it quite possible that without any actual increase of the insanity which is actually certified, there may be considerably more "borderland" insanity and more of that instability of brain which scarcely reaches even this level. He inclines to the belief that more, considerably more, young people of both sexes, break down mentally than there did formerly, but cannot prove it. He should be surprised, he says, if the tables of age on admission into asylums do not show, when they extend over a sufficiently long period, that more patients are admitted under twenty now, than formerly. Dr. Savage, of the Bethlehem Asylum, holds a similar opinion.

— Mme. Trélat, the widow of the late Dr. Trélat, governor of the Salpêtrière Hospital, has recently bequeathed \$40,000 for the benefit of the Paris poor. The rest of her large fortune was left for technical schools for girls, and other public institutions.

\* Practitioner for September, 1886.

them a folded blanket is placed. The feet can rest in the hollows at the top of the foot-pieces or be placed against them and there tied, in case either is used, by passing a bandage over them through the holes *a a*. The catch *c* allows the foot-pieces to be adjusted at any angle. When the patient lies upon them they do not slip in the least, and may be pushed in to shorten or brought out to lengthen, at pleasure. The legs may also be separated more or less at the will of the operator, and retain their position in the most perfect manner. By tying the pieces at *b b* we have a very good support for the legs when the patient is in Sims' position. They can be easily carried to the patient's house, and a good operating table made by placing them on such a one as can be found in any house.

### Reports of Societies.

#### SUFFOLK DISTRICT MEDICAL SOCIETY. SURGICAL SECTION.

G. H. MONKS, M.D., SECRETARY.

MEETING December 1st, 1886, Dr. J. C. WARREN in the chair.

Dr. JOHN HOMANS reported

A CASE OF DUPUTYREN'S CONTRACTION OF THE PALMAR FASCIA SUCCESSFULLY TREATED AFTER THE METHOD OF MR. ADAMS,<sup>1</sup>

and exhibited the patient. He also demonstrated the characteristic deformity on a gentleman kindly brought to the meeting by Dr. Cleaves, of Medford.

Dr. J. C. WARREN remarked, in regard to the etiology of this disease, that it had been regarded as traumatic in its origin, as syphilitic, and also as indicating a gouty diathesis. An examination, by Mr. Noble Smith, of seven hundred elderly inmates of English workhouses, showed seventy to have this malady. He was unable to discover any general condition of health which might have given rise to the disease, although the larger number of cases in which both hands were affected seemed to indicate something more than a local cause. In most cases a contraction of the palmaris longus muscle was observed, pointing to some nerve-irritation. In one case a wound of the fascia had produced a condition identical with the disease, but in many cases there was no history of injury or pressure which might have served as a cause for the disease. Mr. James Hardie recommends longitudinal incisions to expose the contracted bands, which may then be divided and partially dissected out. In two cases there were reports of cure by accidental rupture of the band, the fingers remaining free from subsequent contraction.

Dr. HOMANS also spoke of the possibility of rupture of the contracted bands, and quoted one of Mr. Adams's cases, where they were torn from the palm by violence.

Dr. F. S. WATSON showed a patient, aged thirty-seven, who was the subject of chronic urethritis of some months' standing, and who had had, for seven years,

A CHRONIC HYDARTHROSIS OF BOTH KNEE-JOINTS.

Previous to the appearance of the joint-affection

<sup>1</sup> See page 177 of the Journal.

the patient had had rheumatic fever, but there was an interval of several weeks after the convalescence before the collection of fluid in the joints began to show itself. This came on gradually, without pain, and has been constant ever since. The patient had applied for treatment, the day before, at Dr. Watson's clinic, and he was shown at the meeting simply for the interest attaching to the long duration of the disease, and the comparatively slight injury to the function of the joints, in spite of the great distension of the capsules, and the long time the effusion had lasted. Though the quantity of fluid in both joints was large, yet the increased mobility from relaxation of the ligaments was but slight, and the patient had been able to pursue his trade as a painter without interruption. He had never received any treatment for the trouble.

Dr. HOMANS, in speaking of the difficulty of radically curing cases of chronic effusion into the knee-joint, alluded to a case of his own in which about two tumblersful of fluid was removed by the trocar, and compression applied. For a time the case was supposed to be cured, but eventually the fluid re-accumulated.

Dr. WARREN spoke favorably of the practice of tapping the joint, and of applying compressed sponges afterwards.

Dr. BLODGETT asked, in reference to the formation of fluid in a joint, if it were not possible that, under certain circumstances, there may be an increased amount of fluid without a pathological process being present; that is, simply by an increased physiological action.

Dr. WARREN said he had often noticed that when there was a pathological collection of fluid in one joint, there was a slight increase in the fluid of the other, as if by sympathy.

Dr. WATSON spoke of the frequency of water-on-the-knee at Milton, a peculiarity which had been often remarked.

The rest of the meeting was devoted to a consideration of the ultimate results following the various forms of treatment for suppurative hip disease.

Dr. ROYAL WHITMAN read

A REPORT OF FOUR CASES OF EXCISION OF THE HIP PERFORMED IN 1882,<sup>2</sup>

and showed one of the patients.

Dr. HOMANS considered that Dr. Whitman's work in investigating and reporting the results of such an operation as excision of the hip some years after it was done, decidedly useful. He also spoke highly of the operation, as being the only available mode of treatment in certain obstinate cases.

Dr. E. W. CUSHING showed an Italian instrument, which was specially designed to make subperiosteal sections of bone, and explained how it could be used in excising a hip-joint.

Dr. CABOT said that he entirely agreed with Dr. Whitman in regarding the operation of excision of the hip as a last resort, to be used only in advanced disease, with the object of saving life when death is threatened by the exhaustion of prolonged suppuration. The cases to be cited by Dr. Lovett show what excellent results the expectant plan of treatment can usually accomplish, and it should always be adopted when possible.

Sometimes, however, in spite of the greatest care,

<sup>2</sup> See page 181 of the Journal.

and the most complete fixation of the joint possible with apparatus, the disease shows a tendency to steadily progress to a fatal termination. It is in such a case that a thorough excision, with provision for good drainage of the joint-cavity, is indicated, and will often bring about an arrest of the disease. Sometimes, too, we see a case in which the pain occasioned by the contact of the diseased surfaces of the joint is so great as to rapidly exhaust the patient's strength, and persists in spite of every effort with fixation and extension-splints. Here we have another clear indication for the operation for removal of the diseased parts.

He said that he should differ from Dr. Whitman in regard to the wisdom of stitching the wound carefully together. In an early excision it may be often possible to remove all of the diseased tissues, and so to get a healing by first intention. In the cases, however, in which the operation is justifiable on account of the severity and extensive character of the disease, it is rarely possible to thoroughly remove the suppurating tuberculous material from all of the pockets about the joint, and this being the case, it seems wiser to leave the joint-cavity open and accessible to applications. After a trial of both plans, he has obtained the best results by leaving the wound entirely open, and packing it lightly with iodoform gauze. After excision, as after removal of any tuberculous bone, it is often necessary to do a second operation where the disease is not entirely checked or shows a tendency to return.

Dr. Cabot called attention to the fact that in the case shown by Dr. Whitman there was a lack of development in the limb below, which could not be ascribed to the effect of the operation. For instance, the foot, which was perfectly normal in shape, was about one-half an inch shorter than the foot on the well leg, and proportionately smaller in all of its dimensions.

He said that he had several times noticed an equally marked lack of development of the foot in cases where the knee was affected with white swelling, and where no operation had been done.

Dr. R. W. LOVETT made some remarks on the

#### RESULTS OF THE CONSERVATIVE TREATMENT OF SUPPURATIVE HIP DISEASE.

He spoke substantially as follows:

The published statistics of this treatment give a rather favorable showing in suppurating cases, where the question of excision would come in; the figures are as follows: Gibney, in 1878, reported 80 cases cured by the purely expectant method, or no treatment at all. 48 of these had abscesses, and of the whole number 73 recovered with useful legs. At the Alexandra Hospital 260 cases of suppurating hip disease were treated by rest and extension, 42 per cent. were cured and 33 died. Dr. Taylor, of New York, traced 93 cases from beginning to end. Of the 24 who had abscesses, 2 died, and 17 fully recovered (14 with movable joints) and the other five were doing well at the time of writing. Cazin had charge of the Hospital at Berck where cases of suppurating hip disease were sent from some of the Paris Hospitals after they had ceased to improve. Of 80 cases received, 55 per cent. were cured, that is, the sinuses closed and joint symptoms ceased, and 12½ per cent. died; they were treated by rest and extension. So that suppurating hip disease is not hopeless by any means, even left largely to itself, as in Gibney's cases.

Dr. Lovett then showed two patients from the Children's Hospital, to illustrate average results in severe suppurative hip disease treated conservatively.

CASE I. Harry L., eleven years old. Entered the Children's Hospital, January, 1878, having had hip-joint disease for four months. He was treated by rest and extension in bed, and by a long extension splint at times. Abscesses began to form in a few months and he became worse. Altogether he had fourteen abscesses, and excision was seriously considered but abandoned. He staid at the Hospital for two years, and has now been without his splint for four or five years. He is now a well-developed boy with a marked limp. He has one inch shortening of his leg, his right thigh is three inches smaller than his left, and he has a certain amount of motion in the joint of a very few degrees. But the limb is in a position of permanent flexion of about thirty degrees, and this, of course, makes the limp so noticeable. He is in the soundest possible health.

CASE II. Henry P., seven and one-half years old, came to the Children's Hospital when he was only a year and a half old, having had the disease for six months. He was treated by extension and a Cabot frame. He had two abscesses, and was extremely sick; the question of excision was seriously considered and abandoned in his case too. He staid at the Hospital nearly two years, and he wore his splint for a few months outside after discharge. He is remarkably rugged and well-developed. One leg is an inch and a half shorter than the other, and what is worse, the thigh is flexed on the pelvis at an angle of nearly forty-five degrees. He wears a high shoe, and is able to walk or run any distance. There is no motion in the joint.

Dr. PARKS spoke of a case of suppurative hip-disease he had known of, to be treated by weight and extension for eight years! The result was a favorable one.

Dr. H. W. CUSHING said that the longest course of treatment he could recall, was in a case at the Children's Hospital. For five years the patient was under observation, during which time the treatment was principally by a high shoe and a crutch. The result was satisfactory. He said, also, that he thought excision did not necessarily prevent subsequent general tuberculosis, and quoted an article by Yale in the "Annals of Surgery" for January, 1886.

The advantages of excision, according to advocates of that method, are that the operation prevents general infection, shortens the treatment, and gives better functional results than the conservative method. The conclusions from Yale's article are that the only indication for excision of the hip is to save life.

It does not save the patient from any dangers except those consequent on long suppuration. Hence it is only indicated where the suppurating process has reached a dangerous point, and cannot be stopped by any less serious operation.

Dr. LOVETT remarked that Caumont, in a series of twenty-six cases, excised about one-half, the others being treated conservatively. More cases died of general tubercular infection after excision than after conservative treatment.

Dr. H. L. BURRELL said that regarding the development of tuberculosis after operative procedures, that he was not sure but that the necessary confinement to bed incurred by an operation might not be a factor in

determining its appearance. He had seen five cases of tubercular meningitis develop shortly after the patient had been placed in bed for joint disease, and he had come to look upon placing a patient in bed with joint trouble as a thing to be avoided where possible.

To guard and protect the joint against any jar by some suitable splint, placing the patient under the best hygienic surroundings, opening abscesses when necessary, in fact, thorough conservatism in all the stages of treatment, he believed gave the best results.

Dr. E. H. BRADFORD showed a patient upon whom he had performed

#### SUBPERIOSTEAL AMPUTATION AT THE HIP-JOINT AFTER HIP DISEASE.<sup>2</sup>

After relating the history of the case and describing the operation, he made the following remarks:

The subject of regeneration of bone after sub-periosteal disarticulation at the hip-joint, was considered of so much importance that a committee was appointed by the London Clinical Society to examine Mr. Shuter's case. The committee was unable to satisfy itself of the presence of bone, but recognized a hard core in the stump.

Dr. Bradford therefore requested, that, since the testimony of more than one observer was desirable in all such cases, an examination be made of the stump by the Chairman and Secretary of the Section, and that a report of the same be appended to the full report of the case.<sup>3</sup>

Dr. CABOT spoke of the great value of the *short stump* after subperiosteal amputation, in enabling the patient to wear an artificial limb. He said that Mr. Shuter, in the report of his case, several years ago, stated that the patient had been able to walk considerable distances (two miles); whereas we know that the old methods of hip amputation left no projection to which an artificial limb could be fitted, and that after the late war the survivors from hip amputations were unable to wear with comfort any prosthetic contrivance whatever.

#### QUARTERLY MEETING OF ESSEX NORTH DISTRICT MEDICAL SOCIETY.

MAURICE D. CLARKE, M.D., CORRESPONDING SECRETARY.

The regular quarterly meeting of the Essex North District Medical Society was held at the Eagle House at Haverhill, Wednesday, January 12th, at noon. There was a large and interested attendance, twenty-six members being present. The President, Dr. E. P. Hurd, of Newburyport, occupied the chair, and the records of the semi-annual meeting were read by the Secretary, Dr. George W. Snow, of Newburyport.

The Secretary announced the death, during the past year, of a member of the Society, Dr. Eugene S. Gates, of Lawrence; and on motion of Dr. Crowell, a committee, consisting of Dr. David Dana and Dr. Augustus Stabler, of Lawrence, and Dr. John Crowell, of Haverhill, was appointed to prepare an appropriate tribute to his memory.

It was voted to hold the annual meeting (which occurs on the first Wednesday in May) at Lawrence; and a committee, consisting of Dr. F. B. Flanders, C. G. Carleton, and C. N. Chamberlain, of Lawrence, was appointed to make the necessary arrangements.

<sup>2</sup> See page 180 of the Journal.

<sup>3</sup> See page 181 of the Journal.

Dr. E. W. BULLOCK, of Haverhill, then read a paper upon

#### A CASE OF SCROTAL TUMOR,

occurring in the practice of a Boston surgeon, and which the writer had had opportunity to see daily. The following is an abstract:

John R., forty years old, presented himself for treatment January 5, 1886. He was by occupation a switchman on the Fitchburg Railroad, and subject to much exposure to wet and cold. His habits were good. He used alcohol to some extent, but not excessively. Up to the present time he had been perfectly well and strong. On close questioning he stated that for five years he had noticed that the left side of his scrotum was gradually increasing in size, but, as he had suffered no discomfort from this, he had done nothing for it. Two days after Christmas he attempted to open a switch in the freight yard, and, as the rails were frozen, was obliged to use considerable force to do so. The switch handle suddenly flew back, and, as he thought, struck him on the scrotum. He had a good deal of pain in that region, followed by faintness and nausea, which passed away after a time. On going to bed that night he noticed that the left side of his scrotum was larger than ever before, and the swelling increased during the night. He kept on with his work until the tumor reached such a size as to interfere with the discharge of his duties, when he presented himself for treatment. He had not suffered any pain since the night of the injury. His bowels were regular, appetite good, he had had no nausea nor vomiting, nor any pain in his bowels. His scrotum was much enlarged, the right testicle could be plainly felt, but the left one could not be located. The tumor was perfectly painless, regular in outline, and larger above than below. It extended up to the inguinal ring, but not apparently through the ring. It imparted a decided sense of fluctuation on palpation, but was not translucent. There was no impulse on coughing, nor could the size be at all reduced by taxis.

After the diagnosis had been very carefully considered, it was finally decided that the weight of evidence was in favor of the contents being fluid in character, probably, sero-hæmorrhagic. So it was decided to puncture the tumor, which was done; but only a very little bloody serous fluid was obtained, and the size of the tumor was not materially diminished. The patient was put to bed, and compression tried for a number of days without any success.

At length it was decided to open the scrotum and ascertain the character of the tumor, so, on the 16th of January, he was etherized and an incision made the entire length of the left side of the scrotum. Dissecting down upon the tumor it was found to consist of a large piece of omentum, which extended by a very small pedicle up through the inguinal ring. The pedicle was ligated, cut and allowed to slip back into the peritoneal cavity. The mass of omentum which was removed was about the size of the average adult brain. The wound was dressed antiseptically, and the patient put to bed again. For two days he did nicely, but on the third, for some unknown cause, the temperature rapidly rose, and decided symptoms of septicæmia developed, the wound assuming a very unhealthy condition. He was freely stimulated, quinine given, and the scrotum poulticed. Several abscesses formed in

the scrotum which were opened. On the seventh day after the operation, the temperature fell, and from this time the patient convalesced steadily until he was discharged cured.

The principal features of interest in the case, were the obscurity of the symptoms, and the freedom from constitutional disturbance, which one would naturally expect to follow a hernia of such a size.

DR. MAURICE D. CLARKE, of Haverhill, then read a paper upon

#### HOUSE DRAINAGE.

Whatever conflicting views, he said, might be held by physicians as to so-called filth diseases and as to the relation between sewer-gas and disease, they were as one as to the need of the best appliances for drainage, since no one would take the chances of an open sewer in his bedroom. The multiplication of plumbing devices would imply multiplicity of belief as to drainage, but, in fact, sanitary experts are nearly agreed as to the principle and dispute mainly over matters of detail. As to the deplorable lack of knowledge and interest on the part of the public, the reader cited a case from his own experience. He attended a rapidly fatal case of diphtheria in one of the "fine" houses of the city. The plumbing was examined after the child was dead, and there were found, besides a nearly complete absence of traps and of ventilating pipes, a leaky soil pipe and an open drain in the cellar, which had become choked up and overflowed. Of all this the owner was entirely ignorant.

Certain things in regard to house drainage may justly be insisted on. One is, that the main source (or an important source) of contamination being the house-pipes rather than the street-sewers, there ought to be a trap under every fixture, and as close to it as possible, to reduce to a minimum the unprotected waste-way. Another thing is the necessity for a ventilated soil-pipe, to dilute with fresh air the gas that must arise in all pipes where organic matter is deposited and putrefaction is possible. These two things constitute a most important reform.

With these, one would have reached far toward safety if one could rely on traps for farther protection. Which trap is the best is one that each must determine for himself. The range for choice is wide, and, perhaps, choice is still a matter of some difficulty. The best trap, however, is, other things being equal, the simplest, like other appliances. And the simplest trap, the S-trap with a water-seal, would be sufficient, were it not for certain things that tend to destroy its seal, among which are siphonage, back-pressure, etc., which were well explained by Mr. Putnam, in a lecture before one of the Boston societies last year, a report of which appeared in the *Medical and Surgical Journal*. Siphonage might be obviated by ventilating each trap, but this is likely to destroy the water-seal by evaporation. So-called pot-traps have been devised, but these, like the mechanical traps, easily become clogged. So that, unless one of the new traps, Putnam's for example, proves worthy after full trial, it requires a good deal of judgment to select one with the least faults.

As to water-closets, the writer awarded the old-fashioned pan-closet its appropriate condemnation, any of the newer type of hopper-closets being far preferable. With well-trapped fixtures, a ventilated soil-pipe, and a good water-closet, a man is tolerably well

off. There are, however, other matters worthy of mention. The common set-bowl, with plug, strainer, chain, and overflow-pipe, and the bath-tube equipped with like machinery, are both filthy. Waste-pipes and traps are often too large. Kitchen traps suffer from accumulation of grease. The recent maxim that plumbing should all be in sight or easily visible, was referred to with approval. "In conclusion," said the reader, "it is not to be forgotten that plumbing needs constant supervision and care: the best there is cannot with safety be left to itself. Wash-bowls, bathtubs, water-closets, must be washed and scrubbed like other utensils; soil-pipes watched; traps periodically examined; and the lesson constantly insisted on, to mistress and maid, that health demands the cleanliness which is next to godliness, and which is entirely independent of traps and plumbers."

The paper was followed by an animated discussion, participated in by nearly all the members present, after which the Society sat down to an excellent dinner. Succeeding this, the subject of puerperal eclampsia was discussed, after which the meeting was adjourned.

#### THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting, January 6, 1886. The annual

##### ELECTION OF OFFICERS

was held, and resulted as follows: President, A. Jacobi; Vice-President, William H. Draper; Treasurer, William F. Cushman; Member of the Council, Everetts Herrick; Member of the Committee on Admissions, H. E. Crampton; Member of the Committee on Library, F. P. Kinnicutt.

DR. L. EMMET HOLT read a paper on

#### THE ANTISEPTIC TREATMENT OF SUMMER DIARRHŒA.

In the outset, he wished it to be understood that other methods of treatment than the use of drugs were not ignored by him, though, unfortunately, in the class which suffered the most from this form of disease, it was often impossible to secure proper hygienic conditions, which were so essential to the welfare of the patient. With the exception of instances of pure cholera infantum, the cases of summer diarrhœa, in Dr. Holt's opinion, were all of dyspeptic character, and were primarily due to fermentation or putrefaction in the intestinal tract. Among the factors entering into the causation of the trouble, he mentioned heat, improper feeding, and bad hygienic surroundings. The affection was evidently not due to heat alone, or else we should find that the greatest mortality was among infants under six months of age, which was not the case. During the first six months a much larger proportion of infants were wet-nursed than at a later period, and it was after this age that the greatest mortality from summer diarrhœa was noted.

In treating of the influence of heat, he spoke of its effect upon the food, as well as upon the child, and referred to an instance at the New York Infant Asylum, in which no less than twenty-three children became affected with diarrhœa in a single day, from the use of tainted milk. In tenement-houses, all the conditions were especially favorable to the contamination of this article of food, and it was remarkable that more children did not suffer from this cause than was

actually the case. In this connection, he spoke of the development of poisonous ptomaines from food, and alluded particularly to the investigations of Professor Vaughan, of the Michigan State Board of Health, in regard to the principle which he has designated as tyrotoxin. Bruntton's researches had also, he thought, furnished the solution of many hitherto insoluble problems. Cerebral symptoms had been generally supposed to be due to the sudden stoppage of the diarrhoea. Huchard had shown, however, that poisonous ptomaines were involved from human faeces in conditions of health, and this was the case to a much larger extent in disease.

In summer diarrhoea, Dr. Holt went on to say, the inflammatory changes were almost entirely confined to the large intestine. A specific microbe bearing a causative relation to the affection had not been as yet demonstrated, though numerous bacteria, of various kinds, were always found in connection with it. The indications for treatment were as follows: (1) Clear out the bowels; (2) stop decomposition; (3) restore healthy action to the bowels; (4) treat the consequential lesions. In the first place, it was necessary to clear out the bowels, for the same reason that the surgeon thoroughly cleanses a wound before applying his antiseptics. As a rule, Dr. Holt said he began his treatment with a cathartic, in order to remove the altered secretions; and if the stomach was not very irritable, there was nothing which, in his opinion, was to be compared to castor oil for this purpose. If the stomach were irritable, he was in the habit of using large injections of water by means of a fountain-syringe. By experiment, he found that it took about a pint of fluid to reach the ilio-cæcal valve, and, at least, this quantity should be used. In many cases the castor oil was all the medicine that was required, as a suitable dietetic and hygienic regimen would do the rest. In cases in which the passages, consisting of pure serum, were odorless, and alkaline in reaction, no preliminary cathartics were required.

In order to stop decomposition and restore healthy action in the bowels, the most efficient agent that he had found was the salicylate of sodium. If there was much vomiting, it was better to withhold food altogether from ten to twenty-four hours, employing carbonic acid, water, or thin barley-water, for allaying thirst. In children under two years of age no milk whatever should be allowed, though peptonized milk was much less likely to do harm than either condensed or ordinary cow's milk. He had known many relapses to be brought on by the use of milk.

The treatment of the consequential lesions was the fourth point considered. This consisted in (1) appropriate dietetic treatment; (2) the continuation of the antiseptic; and (3) the washing out of the whole large intestine every day with pure water, or with a weak antiseptic or astringent solution. The medicinal agents which he preferred for these injections were benzoate of soda and nitrate of silver. It was a fact, he said, that all the drugs which had formerly proved of service in the treatment of summer diarrhoea, with the exception of opium (in regard to which there had been much discussion), were of a more or less antiseptic nature.

Dr. Holt then proceeded to give a *résumé* of the history of the use of antiseptic remedies proper in this affection, from the time when Mays first employed creosote, in 1846. As long ago as 1853, Matthison

had reported much success from the use of salicin, and in 1858 S. W. Smith published, in the *British Medical Journal*, his successful experience with willow charcoal. In 1879 Kilner used salicylate of bismuth and calcium, and in 1880, Hutchins, of Brooklyn, reported good results from the use of salicylate of calcium alone. Segur, of Brooklyn, also met with much success in the treatment of the diarrhoea of phthisis with salicylates. In 1886 Braithwaite recommended the use of salicylate of iron, which he had found very efficient. Naphthaline had been highly lauded by Falkenberg and other writers, and bichloride of mercury had also been recommended by Ringer and others.

Even the most recent text-books on diseases of children, Dr. Holt went on to say, advocated practically the same treatment of summer diarrhoea that was in vogue fifty years ago. In order to find out what was the present practice in New York institutions, he wrote to the physicians of fourteen of these, including the Nursery and Child's Hospital, the Foundling Asylum, St. Mary's Hospital for Children, the Demilt Dispensary, and a number of other prominent hospitals and dispensaries, in which upwards of 40,000 children are treated annually—25,000 for diarrhoeal diseases. He found, among other facts, that opium was used in all, and bismuth in all. Castor oil, as a preliminary medication, was used in six; and castor oil emulsion, with equal parts of the oil and paregoric, in three. Chalk-mixture, in combination with paregoric and astringents, was used in several, calomel in three, ipecac in three, pepsin in one, iodoform in one, morphia and atropia, hypodermically, in one, and astringent injections in three.

Dr. Holt said that, in his own experience, he had found that with the use of opium, bismuth, and astringents, fifty per cent. of cases were cured, and seven per cent. died. A year ago last summer he first commenced the use of salicylate of sodium. In about two-thirds of the cases in which he had employed it he gave castor oil as a preliminary to the treatment. In a few cases, where there was great nervous irritability, he employed Dover's powder, simply for the purpose of controlling this. Out of eighty-one cases treated with the salicylate, sixty were cured, fourteen improved, six not improved, and one died. The results of all his cases were as follows: cured, eighty four per cent.; died, one per cent.

Of 44 cases in which he had employed naphthaline, 67 per cent. were cured, 15 per cent. were improved, 13 per cent. were not improved, and 1 per cent. died. In 27 cases treated with resorcin, 22 per cent. remained unimproved, and it soon became evident to him that this agent was not nearly so efficient as either salicylate of soda or naphthaline. He had also used bichloride of mercury in 28 cases, but had not found it as successful as the remedies named. The comparative results of treatment of these different remedies were, then, as follows: Cured by opium, bismuth, and astringents, 50 per cent.; cured by salicylate of sodium, 84 per cent.; and by naphthaline, 67 per cent.; cured by resorcin, 55 per cent.

After relating an illustrative case in which the salicylate of sodium, administered after a preliminary dose of castor oil, had effected a cure in an apparently hopeless case, Dr. Holt stated that he was in the habit of giving the salicylate in doses of from one to three grains, every two hours, and in the form of an aqueous solution which could be taken with the food

or drink. Instead of producing vomiting, he had found that it often allayed irritability of the stomach. Naphthaline could be given in doses of from half a grain to five grains, and resorcin in doses of from half a grain to two grains. Bichloride of mercury, which was given in doses of from  $\frac{1}{16}$  to  $\frac{1}{8}$  of a grain, was sometimes apt to produce vomiting.

The putrefactive changes taking place in the food, which was the immediate cause of summer diarrhoea, often began outside of the body, before it was eaten; and diarrhoeal discharges at the outset, at least, were to be regarded as salutary. Dr. Holt mentioned that he did not undervalue the efficacy of opium in other forms of diarrhoea. In conclusion, he said that the use of evacuants constituted an essential part of the antiseptic treatment; and, as the result of his experience, expressed a preference for the salicylate of sodium after a cathartic had been employed. The antiseptic treatment he regarded as especially valuable because it removed the cause of the trouble in the intestinal canal, and did not simply combat its effects.

DR. WILCOX related his experience with naphthaline, in the treatment of diarrhoea; stating that he had employed it in thirty-two cases, nearly all of which, however, were in adults. In his hands it had proved so efficient that he had come to regard it of the same value in diarrhoea as mercury in syphilis, or quinine in malarial trouble. In order to secure its full effect the patient should take at least sixty-grains a day, and in some cases as much as one hundred and twenty grains *per diem* was required. He gave it chiefly in starch capsules, with oil of bergamot to conceal the odor. Occasionally he had found that the urine became smoky under its use, but no albumen or casts could be detected in it. In one case of twenty-four years' standing, in a man sixty-one years of age, a cure was effected by the use of ninety grains a day. In two cases he had used it successfully in the diarrhoea of typhoid fever. The patients were in the third week of the disease, and took from sixty to ninety grains a day, which reduced the stools to two in the twenty-four hours, and rendered them perfectly odorless. Naphthaline also had an antipyretic effect in these cases, and he regarded it as quite as safe as any of the antipyretics now so commonly employed, such as antipyrine, thallin, etc. He had also tried resorcin to some extent, but with very indifferent results.

DR. ANDREW H. SMITH remarked that it had been his idea for some time that the cause of summer diarrhoea could be best treated by the aid of antiseptics. The essential oils which were in common use in domestic practice, are really antiseptics and the same was true of the pennyroyal, spearmint, and peppermint teas so often resorted to in the country.

DR. VAN ZANTWOOD said that Dr. Holt was no doubt correct in considering the disease primarily dyspeptic in character. He thought bismuth was of service, not simply from its mechanical effect, but because it was a true antiseptic. The inflammatory changes were largely located in the large intestine, and he was in the habit of employing large astringent injections to flush out the colon. He combined an alkali with the astringent in these injections, in order to be able to get at the mucous membrane, by removing the mucus from it.

The President, DR. A. JACOBI, said that he heartily agreed with what Dr. Holt had taught in his paper, and particularly as to the antiseptic character

of remedies long in use. As regards bismuth, which is now regarded simply as an inert mechanical substance, he had published an article twelve years ago in the *American Journal of Obstetrics*, in which he distinctly claimed that it was an antifermentative; and such was still his conviction. He also agreed with Dr. Holt as to the importance of appropriate dietetic treatment. If there were any one especial danger in summer diarrhoea, it came from the use of milk, and for twenty-five years now, he had taught that the disease could not be cured unless milk was given up. It was often necessary to withdraw it for a number of days; and there were plenty of things that could be resorted to to take its place. As a rule, he substituted for it the white of egg, raw, mixed with barley water, or other farinaceous drink. The use of raw meat had been advised by some, but this should not be employed if it could be avoided, on account of the danger of introducing into the system the *tania canelata*, which was a much more difficult kind of tape-worm to get rid of than the ordinary *tania solium*.

DR. GEORGE F. PEABODY said that he had come to look upon naphthaline as a very valuable addition to our therapeutic resources, in a number of intestinal complaints. For some time past he had been using it in all the earlier cases of typhoid fever which came under his care at the New York Hospital. It was reasonable, he thought, to look for relief in a remedy which acts directly on the local lesions, and several cases had already occurred in his practice in which the disease was apparently aborted by this remedy. He referred particularly to a case which came under treatment on the second day of the disease. By the thirteenth day the fever was gone, and convalescence had commenced; yet the patient had had the usual prodromal symptom of typhoid, and the characteristic eruption and enlargement of the spleen had been well-marked. Dr. Peabody also mentioned a case of chronic diarrhoea, of twenty-one years' standing. The patient had been under treatment for a broken leg in the surgical wards of the hospital, but though while there the usual astringent remedies were employed, the diarrhoea still continued unchecked. On his transferral to the medical wards he was placed on the use of naphthaline, and in ten days the case was cured; the passages by that time having become normal in quantity, color, consistence and odor. Having referred to another cure of chronic diarrhoea by naphthaline, he stated in conclusion that all his cases of typhoid fever were given a preliminary full dose of calomel.

DR. HOLT said that Dr. Cauldwell, whom he had expected to be present at the meeting, had used salicylate of sodium with much success, in twenty cases of the diarrhoea of phthisis.

— In a recent paper by Prof. von Nussbaum, of Munich, on "Erysipelas," the author speaks very highly of the use of ichthyol, in the form of an ointment, made of equal parts of ichthyol and vaseline, to be painted over the whole erysipelatous area, then covered with ten per cent. salicylic lint, and fixed with a gauze bandage. In erysipelas of the face, ichthyol collodion is to be preferred, and on the hairy scalp, ichthyol soap.

**ANNUAL REPORT OF THE SURGEON-GENERAL, UNITED STATES NAVY.**

The report of the Surgeon-General, with the appended documents and estimates, makes a volume of 126 pages; but the report itself is apparently based on the size of the Navy.

The most noticeable recommendation is one to increase the advantages and improve the condition of the Medical Corps of the Navy. Its vacancies have not been filled for several years; resignations, deaths, and retirements have depleted it more rapidly than candidates have been obtained. The Bureau has not been willing to lower the standard of requirements, and it is impossible, with the present inducements, to find young men of the necessary qualifications who are disposed to become medical officers of the Navy. The Army has properly-qualified applicants in excess of its needs; its superior qualifications being better pay, well-defined rank, and more satisfactory professional position. Since 1870, more than thirty young medical officers have resigned, three of them to enter the army corps.

Of the persons examined for enlistment during the year — 10,913 — 79 were rejected for color-blindness or feeble color-sense. Eight candidates for admission to the Naval Academy have been rejected during the last four years for a similar cause.

The Medical Corps of the Navy is doing its share in advancing the public welfare through the Museum of Hygiene. In his report, Medical Director Turner, who is in charge of the Museum, states that there has been hardly a day without some call for information, either from plumbers, architects, medical men, or others interested in the means of preventing dangers to health. The collection of sanitary and hygienic appliances has increased, until the present building is completely occupied, and the attic is crowded with unbroken packages. In the library the shelving is full, and the constant addition of books, pamphlets, and circulars upon hygiene, both general and especial, has rendered it necessary to store these accessions upon

the floor space. In fact, its overcrowded condition impairs its usefulness.

The researches in the chemical, physical, and biological departments of the laboratory, which forms one department of the Museum, take the widest range, and may become of national importance; but the advantages of the Museum to original investigators, and their investigations into matters connected with public health and the progress of preventive medicine, are at present at their minimum for want of working room.

**EXTENSION OF THE CROTON WATER-SUPPLY SYSTEM.**

At a meeting of the New York Aqueduct Commissioners, held February 7th, it was formally determined to go on with the construction of the great Quaker Bridge Dam, which has been so long in contemplation as a part of the Croton water-supply system. On account of the magnitude of the work — the most stupendous piece of engineering of the kind ever undertaken — the Commissioners have proceeded with great deliberation, and did not finally decide in regard to the matter until after abundant opportunity had been afforded for the expression of the opinion of experts favorable to and in opposition to the project.

At the meeting there were presented a majority and a minority report. The former, which was in favor of the construction of the dam, was signed by six of the seven Commissioners. In it reference was made to the fact that some of the best hydraulic engineers of modern times have approved of the plan, and Gen. Newton, who recently resigned his position as Chief of the Engineer Corps of the United States Army, to accept the position of Commissioner of Public Works of the City of New York, supplemented the report with a personal statement favoring the project as the best one for securing a requisite supply of water for the city. In the minority report, which was signed alone by Mr. Spencer, President of the Aqueduct Commission, it was claimed that the construction of the dam, besides entailing an expense of over ten million dollars, was open to the objection that the dam would enclose an enormous quantity of water which could not be distributed in a thoroughly pure condition. In answer to this sanitary point a letter was read from Prof. Charles F. Chandler, ex-President of the New York Board of Health, in which he commended the project and denied that the water distributed from the lake formed by the dam would be impure.

The great dam which it has thus been decided to construct, will be situated several miles below the present Croton Dam, and near what is known as the Quaker Bridge. The dimensions are to be as follows: Total height above foundation upon solid bed rock, 277 feet; height above the bed of Croton River, 178 feet; length of dam at foundation, 500 feet; length at top, 1,500 feet. Including the capacity of the Muscoot Reservoir, which it was also voted at this

meeting to construct, 2,500,000,000 gallons, and of the Croton Reservoir, 1,500,000,000 gallons, the new dam will make a reservoir of the capacity of 38,377,935,000 gallons. The dam will raise the water 34 feet above the Croton Dam, and the surface-level of the water in the new reservoir will be about 200 feet above mean tide on the Hudson River. The plan for the water-supply of the city, as at present contemplated, will add 23 square miles of territory to the watershed of the Croton River, and the cost of the entire work, including \$1,200,000 to be expended in the purchase of the land required, is estimated by Mr. Church, the chief engineer, at \$6,741,000.

#### MEDICAL EXAMINERS AND THE RECORD OF THEIR WORK.

Two years ago, the Legislature of Massachusetts enacted a law requiring medical examiners to transmit annually to the Secretary of the Commonwealth "certified copies of the record of all deaths," the cause and manner of which they had investigated in the course of their official duty during the previous year. To secure uniformity in these annual reports, blank forms are provided which are designed to facilitate and systematize the work, at the same time leaving to the medical examiner a considerable discretion touching the fullness of the details relating to individual cases, the heading "Notes" permitting a somewhat elastic interpretation, according to the facts actually in the possession of the reporter and according to his judgment of the relative importance of the case itself. Thus, a homicide deserves fuller notice than a case of accidental drowning, and the blank, after its requirement of data relating to name, age, time of inspection and of autopsy (if an autopsy is made), cause and manner of death and expenses of the investigation, leaves an unlimited space for the full history of the case, the anatomical appearances, the result of the inquest and of other judicial proceedings—in short, a complete medico-legal history of the individual affairs.

Now it is obvious that these records—if properly made and successfully edited and published, as the law contemplates—must be of very great value to the medical examiners themselves, by leading them to be closer observers, knowing that their work must go on record; to the executive department of the State government, by demonstrating the fitness of individuals to hold the responsible office of a medical examiner; to legal medicine, by furnishing a unique collection of medico-legal cases; to medical science at large, by throwing light upon a too-neglected but fruitful field; to the public in general, by supplying evidence of the efficiency and fidelity displayed by its servants. The labor imposed by the statute upon the medical examiner is not a burden worth mentioning, a majority of the corps having but a limited number of cases in the course of each year; it is only in the large cities that the task of preparing the records can prove in any degree irksome.

An examination of the returns on file at the office of the Secretary of State, covering the work of the year 1886, compels the conviction that, on the part of some of the medical examiners, the purpose and potential advantages of the law are not recognized or appreciated. The letter of the statute has, indeed, been fulfilled, but its spirit and intent have been in too many instances ignored. In some cases, the "certified copy of the record" gives a most meagre and wholly unsatisfactory mention of the circumstances attending the death; in a few instances, the return has been forwarded with absolutely no mention of the data having medico-legal value, the column of "Notes" being left blank.

This evidence of indifference or laziness is exceptional, however; the majority of the reports are satisfactory, and attest the zeal and intelligent efficiency of their authors. But it is plain that, unless all the corps of seventy-four medical examiners freely and faithfully contribute their share to the general fund of medico-legal information, the product is just so far impaired. If the raw material, the foundation data, are of poor quality, it is useless to look for fine results at the editor's hands. Each medical examiner owes it to his fellows, to the honor of his office, and to his respect for the law, to make his record of real value.

The JOURNAL's uniform attitude of friendly recognition of the medical examiners and their work, makes it a less ungracious act to give this hint of the possibility of improving that work in one important direction, and to recall the adage "Whatever is worth doing at all is worth doing well." If the new system of investigating deaths by violence is to grow in esteem in the State of its birth, and is to commend itself to other States as a good thing for their adoption, it must continue to enlist the efficient, zealous, faithful services of its own agents and representatives.

We continue to be so convinced of the excellence of the system, as a whole—of the great advance over the conditions which it has replaced—that we earnestly desire to see it bearing *all* the results which we know may be fairly expected from it. And while we believe it to be better that medical examiners should not be cramped and trammelled by a too rigid official formulæ, we should be glad to recognize that they were all availing themselves, in the best sense and with the most genuine discretion, of the latitude which the present forms allow. We hope that all our medical examiners will feel a just pride in keeping Massachusetts to the front in this very important department.

#### THE HYGIENE OF CRIMINAL COURTS AND PRISONS.

DR. DAY, Sanitary Superintendent, has transmitted to the New York Board of Health a report by the Sanitary Inspectors in regard to the condition of the Tombs Police Court, the Special Sessions Court, and the old Tombs Prison, the result of an examination

just made in compliance with a request of the Board of Police Justices. The inspectors found the places named in a deplorable and alarming condition. Thus, there are old brick cesspools full of disease-breeding matter under the police court, and apertures in the walls permit the effluvia to enter the court-room. This room, in which 26,000 persons were arraigned last year, is badly ventilated; while the sewerage is in a disgraceful condition. All the waste-pipes of the prison seem to connect directly with the Special Sessions Court and the clerks' offices. The connections are not trapped, and there is free communication with unventilated house-drains which empty into a large pool in the prison yard. The heating system, which is by stove, also further vitiates the air.

This report, which states furthermore that the recommendations made in regard to the Tombs, two years ago, were only partially carried out, and explains what measures should be adopted for the removal or improvement of the bad sanitary conditions now prevailing, was transmitted by the Health Board to the Commissioners of Charities and Correction, and it is to be hoped that prompt action will be taken in the matter.

So long as conditions, such as those described in this report, continue to prevail in our court rooms and jails, we shall continue to find in practice that members of the bench and bar, especially in middle life, are peculiarly liable to pneumonia, and to read in our text-books that phthisis flourishes in prisons; even if we escape a revival of the old term, jail-fever. Bad ventilation is probably the rule rather than the exception in most of those buildings in our cities devoted to the detention of criminals and the administration of criminal justice; add to this overcrowding and bad drainage, and all the necessary conditions are given for producing a rapid rotation in judicial offices, with an early transference to another world of the administration of justice. It may be because such results are not recognized as an absolute evil, that it is so difficult to arouse the spirit of reform.

#### MEDICAL NOTES.

— Dr. Schutz, of Rostock, advocates the use of hydragric acid in many cases of profuse menstruation, and also in the hemorrhages from myomata. He believes that it acts primarily on the bloodvessels, while ergot acts on the muscles of the uterus. Thus the two drugs produce similar effects, but in different ways, and the hydragric has been found sometimes effective in cases where the ergot failed.

— The editor of the *Therapeutic Gazette* says that in several hundred cases of chorea treated in the Philadelphia and University Hospitals, cimicifuga racemosa was found of some value, but yet was distinctly inferior to arsenic. If this latter remedy fails, the next attempt is usually made with the cimicifuga. The arsenic, however, requires to be given in ascending

doses until it produces physiological effects, which requires a little boldness on the part of the physician. If the remedy is withdrawn as soon as puffiness is seen in the face, no harm can be done.

— Not long since an action was brought at Paris to recover a sum of money alleged to be owing as the price of the sale of a medical practice. The plaintiff was non-suited, on the ground that the *clientèle* of a physician was not a saleable property, and, therefore, that the money agreed to be paid in consideration thereof was not recoverable by law. This ruling is in marked contrast with the usage so common in England of transferring physicians' practices, and is somewhat in accord with the experience in the comparatively infrequent operations of the kind in this country, that it is one thing to make the sale, and quite another to deliver the goods.

— The abstract of sanitary reports issued from the office of the Surgeon-General of the Marine Hospital Service, under date of February 17th, gives the returns as to cholera in Japan. In 1885 there were altogether 11,927 cases and 7,152 deaths, the proportion of mortality being about 60 per cent. In 1886, there were 154,373 cases and 101,695 deaths, a proportion of about 66 per cent. Thus we see that the cholera in Japan during the past year has spread widely, has been exceptionally severe, and the percentage of deaths enormous. In Nagasaki Ken, however, owing to the speedy and vigorous restrictive measures adopted by the Government, the epidemic of 1886 was not so severe as that of 1885.

The means taken for the control of the disease at Takasima Colliery, on the island of Takasima, near Nagasaki, were particularly creditable. At this place, in 1885, the epidemic had been very severe. Of the 4,000 men employed in the mines 1,500 were attacked and 800 died. As this was the third or fourth time that the island had been ravaged with cholera, the owners of the mines determined to try such preventive means as modern science could suggest. A complete sewerage system was formed. Heavy pumping arrangements were erected on the beach, for pumping sea-water to the highest point of the island, whence by an arrangement of drains and sluices it was gravitated back to the sea, flushing for three or four hours daily every drain among the dwelling-houses. An extensive fresh-water condensing apparatus was erected, turning out from 7,000 to 8,000 gallons of water per day. The wells on the island were closed, and water from the main-land only allowed to be imported for purposes of washing, etc. A strict system of food quarantine was instituted, and all food was supplied through the company. Three digesters, each of 800 gallons capacity, were erected, beef killed under inspection being used to make soup, about 1,000 gallons per day being supplied to the miners. Beef was also served out in the rations. All shell-fish were prohibited, only deep-water fish, after inspection, being allowed to be landed or sold. No deleterious vegetables of any kind were permitted to be brought

to the island; potatoes, beans, and certain harmless native vegetables being the only ones allowed for consumption. The success of the system adopted has been amply demonstrated by the fact that Takasima has been the only place in Nagasaki Ken untouched by cholera during this year's epidemic.

## BOSTON.

— We observe that one of our New York contemporaries has taken somewhat seriously the sensational report published in one of the Boston daily papers, to the effect that a bureau of undergraduate practitioners had established itself in proximity to the Boston Lying-in Hospital, on McLean Street, with a view to diverting obstetric patients from that institution. We had refrained from allusion to this unfounded story when it appeared, but, as it seems to have impressed the very elect, we now refer to it only to deny its authenticity. Practice in a dispensary district and instruction in obstetrics appear to have confused and been confused in the mind of an enterprising reporter.

## NEW YORK.

— Dr. J. B. Mattison, of Brooklyn, read a paper on "Cocaine Dosage and Cocaine Addiction," before the Kings County Medical Society, February 15th; and at its close, a motion made by Dr. Alex. I. C. Skene was unanimously adopted, appointing a Committee, consisting of the President and Secretary, Drs. Wallace and De Laverne, and Dr. Mattison, to draft a bill for presentation to the legislature, placing cocaine on the list of poisonous drugs, and to be sold only on physician's prescription.

— At this meeting the Society adopted the report of a Committee recommending the purchase of land and buildings on Bridge Street, and appointed Trustees to make this purchase and to receive subscriptions, not to exceed \$15,000. It is intended to erect a large hall for meetings, and transfer to it the Society's library.

— Small-pox does not seem to increase in the city, but still prevails to some extent. During the week ending February 19th, there were reported thirteen cases and six deaths from the disease.

— At a meeting of the Institute of Social Science, held February 10th, Dr. T. D. Crothers, Superintendent of the Walnut Lodge, Hartford, Conn., read a paper on the "Cause and Cure of Inebriety." He estimated the number of inebriates in the United States at 500,000, with a mortality of 90 per cent., and assigned a number of causes for the existence and increase of the evil. He considered inebriety as a disease, which is not curable by the exercise of will-power, and advocated the organization of work-house hospitals, in which the inebriated could be restrained and treated, these institutions to be situated in the country, and conducted on a military basis. He would have three grades of hospitals: one for recent cases, where the inmates can be committed by the courts, or volun-

tarily commit themselves, for one or two years; another for chronic cases, with a term of commitment of from one to three years; and the third for incurables, with a term of from five to ten years, or for life. The money for their maintenance would be taken from the license fund or the taxes on the sale of spirits.

## Miscellany.

## CHLORAL HYDRATE AS A VESICANT.

ATTENTION is again called by the *Medical Press*, October 13th, 1886, to the fact that, for blistering purposes, chloral hydrate is fully as efficacious as cantharides, while it is free from the inconveniences attending the employment of this latter agent. The chloral should be reduced to a powder, and a layer of it placed on a piece of common adhesive plaster, taking care to leave a margin between the edge of the layer of chloral and that of the plaster. This is then warmed over a gas-jet until the chloral becomes discolored and melts, when it should be immediately applied on the spot for the operation, the skin covering which is to be anointed beforehand with olive oil or lard. The anæsthetic properties of the chloral prevent any unpleasant sensation, and fifteen minutes is the maximum period of time during which the application may be continued. If the above-mentioned precaution be taken of anointing the skin, its vitality is retained, and the presence of an open wound is avoided, the skin adhering again as soon as the exudation is evacuated. Another advantage consists in the absence of the risk of poisonous effects consequent on absorption, a by no means uncommon sequel to the use of cantharides.

## THE OCCASIONAL SUPERVENTION OF URGENT SYMPTOMS UPON THE PUNCTURE OF HYDATID CYSTS OF THE LIVER.

MR. LAURENCE HUMPHRY reported in the *Lancet*, January 15th, a case of collapse with dangerous symptoms, following the withdrawal of half a drachm of hydatid fluid by means of a hypodermic needle from the liver of a man aged twenty-three. He also cites two cases in which death followed this simple operation, while the occurrence of urticaria after such puncture is said to be common. He thinks that these complications do not arise after the puncture of other hepatic tumors or abscesses, and believes that the hydatid cyst contains some poisonous substance which finds entrance to the system at the time the cyst is tapped. To confirm this he requested Professor Roy to inject into animals (in the jugular veins and the peritoneal cavity) some of the fluid from this patient. Two of the animals died and the others showed toxic symptoms. As a conclusion from his experiment Professor Roy remarks: "It may be concluded from this experiment, so far as is possible from a single experiment, that there is in hydatid fluid some substance which has a powerful effect on both the heart and the respiratory mechanism. From the first two doses but little effect on the rate of the heart-beat was produced, but on giving a larger dose the slowing of the heart from

seventy to thirty-three beats per minute is very striking. The acceleration of the respiration by the first dose and its great slowing by the dose of twenty cc. of hydatid fluid, are also remarkable. The great fall of the blood-pressure after the third dose shows that the fluid from hydatid cysts contains some substance which can affect the blood-pressure in the systemic arteries to a very serious extent. The marked change in the rate of heart-beat, the respiration, and the blood-pressure after atropine seems of much interest as well as of practical importance." The hydatid fluid may enter a wounded vein at the time of puncture (continues the author), or escape into the peritoneal cavity and be subsequently absorbed, and the rapidity of onset and urgency of the symptoms would be the indication. In the post-mortem account of the fatal case recorded by Mr. Bryant, it was found that immediately inside the hydatid capsule the trocar had transfixed a very large vein, which on subsequent dissection was found to be the trunk of the portal vein, and it was supposed that after withdrawal of the trocar, hydatid fluid escaped into the portal vein and acted as a fatal poison. It may be questioned whether there is not a greater liability, where the close method of tapping is employed, for the fluid to find entrance into one of the dilated veins, which are sometimes found in the fibrous atrophied liver tissue around the cyst, should one happen to be wounded; and whether the treatment by incision, advocated by some, may not be found safer.

#### PHYSICAL TRAINING IN ELEMENTARY SCHOOLS.

THAT this important subject is gradually gaining public attention, is sufficiently clear to one who reads the signs of the times. What is especially needed is evidence as to what specific means of training have been tried and found applicable in common schools. In this direction is an article by Charles F. Bearsley, M. A., in the *Sanitary Record* for December 15th, 1886. We make the following extracts from the article:

"No one who has visited one of the newest and most efficient of our Board Schools can fail to have been impressed by the thoroughness of the arrangements and the completeness of the educational machinery, so far as it goes. At the same time it would not be strange if one came away with the feeling that there is a onesidedness about the whole system. This imposing building, with its ingenious apparatus and skilled staff, is devoted entirely to the training of the mental faculties. As a rule, the physical development of the scholars is left to take care of itself. Reading, writing, arithmetic, history, geography, grammar, in some cases the elements of science, even languages, as well as drawing, sewing, and cookery, are taught after the most approved methods. In nearly every time-table systematic physical training is conspicuous only by its absence.

"If physical exercise is to be generally introduced into our elementary schools, it must be put on an equal footing with other subjects. Then teachers may devote a fair amount of time and attention to it without being harassed by the thought that for the time thus employed they will be able to show no pecuniary result.

"If physical training were to be thus endowed as a

source of school revenue, it might be considered necessary to have, as a guarantee that some definite work would be done therefor, a syllabus of exercises for each year. A suitable scheme could easily be arranged. Probably much might be learned from a study of the German and Swedish systems of gymnastics. It might, however, be better at first to leave the scheme of exercises to be arranged by the teachers, subject to the approval of the school inspector. I do not at present propose to offer many detailed suggestions, but shall confine myself to a few general principles that should be kept in view.

"In the first place the exercises, while tending to the healthy development of all the bodily organs, should be, as much as possible, of a recreative character. In the younger classes they must be very largely so, just as the kindergarten system seeks to educate the senses and the intellect by attractive exercises in form, color and number. Some actual pastimes might be occasionally introduced, and the charm of combined rhythmic movement should not be forgotten. It is generally understood that exercise taken for its own sake is not so beneficial as when it is incidental to some pleasant occupation or the attainment of some engaging end. Of course there must be a good deal of routine work in any practicable scheme. Even though it were found unavoidable that the course should consist entirely of gymnastic drill, it might still be expected to be attended with solid benefit. A great part of the intellectual training of children has to be conducted on the 'drill' principle. Drill there must be; but the regular change from mental to physical drill would do much to refresh the jaded powers of both scholar and teacher. I say 'teacher' advisedly, for the teachers should share in all the exercises and in all the sports of the children. It is in fact almost as much in the interests of the teachers as of the scholars that I desire to see physical training made a regular part of our school system.

"On this account I would strongly recommend that the exercises be taught not by visiting teachers but by the ordinary staff. There is another reason for this, well known to practical educationists. Visiting teachers are generally regarded as a kind of necessary evil. They have not the same hold of the children as those who have them constantly in hand; often, though perhaps eminent specialists, they are unskilful in teaching and dealing with children; and the arrangements necessary for them to meet the scholars in suitable detachments often interfere seriously with the organization of a school. A system of physical training which necessitates such aid is bound to break down. To insure its success it must be workable by the ordinary staff. Gymnastics and calisthenics, which are not at present entirely neglected in our training colleges, would then become subjects in which proficiency would be desirable; and there is no question that in a short time teachers thoroughly qualified for the work would be turned out. . . .

"Lastly, as to apparatus, rooms, etc. A good many invigorating exercises require no apparatus. For a good many others apparatus could easily be fitted up in the ordinary class-rooms. Many exercises on the parallel and horizontal bars, as well as vaulting and leaping, could be performed by a class in rapid succession. On a row of rings or stirrups, suspended along the free space of a class-room, the pupils could exercise themselves in detachments. Any additional

outlay on appliances of this sort should be regarded as a part of educational expenditure as necessary as the cost of a desk and seat for each scholar. A regular gymnasium would no doubt be a great acquisition to every school; but it is by no means indispensable. Even where there is one, part of the exercises should be performed in the class-rooms; and it would be desirable to have a considerable portion of the training given in the open air.

"Of the feasibility of the scheme suggested I have, as a practical teacher, no doubt whatever. It is quite as workable as the present elaborate sewing schedule, and much more so than the teaching of cookery in elementary schools."

### Correspondence.

#### THE DISCUSSION ON ARSENIC AT THE SUFFOLK DISTRICT SOCIETY.

BOSTON, FEB. 19, 1887.

MR. EDITOR,—In your issue of February 10th, an editorial upon "Arsenic Wall-papers" comments upon my remarks at a meeting of the Suffolk Section of the Massachusetts Medical Society. Presumably these comments were based upon the report of the meeting as published in your paper. The report so distorted what I said, and in several instances made me say what I did not say at all, that I make claim to your space in correction.

In regard to the several disorders instanced as having common symptoms, I did not say that physicians made mistakes, but used the words, "how are you to differentiate in these cases."

Neither did I say that this subject is "but two or three years old," for a correct report would show that I instanced a case of twenty years ago; and here I was made to say that "the girl died." Any reader could see that if I had desired to show the "careless way" and "wrong theories" of physicians, I should not have added by way of context such a remark as "the girl died." In point of fact the girl did not die. What I said was "the symptoms still remained," and I further added, "no attention was paid to the fact that there was a washstand in the bedroom connected with the sewer."

In speaking of the arseniuretted-hydrogen theory of poisoning I dismissed it with the simple remark: "It is ingenious, but I think hardly probable."

It is not necessary to enlarge upon the various other points. I may, however, add that the method of production of arsenical aniline colors, as attributed to me, is mistaken.

To your editorial upon the subject I need not refer in detail. After the distortion of the report, it follows naturally enough, I suppose, that you should use such words as "ignorant" and "impertinent;" but it is considered more courteous to first be accurate in understanding one's position if it is to be assailed. I do not feel it desirable at this time to treat the question controversially, and have avoided statements in support of my position.

At the meeting of the Society, my treatment was marked by courtesy and attention, and I have been surprised that the report of my remarks was so generally perverted. In fact, there are only one or two sentences which convey the sense of what I said.

C. TENNANT LEE.

[Mr. Lee's remarks at the meeting of the Clinical Section of the Suffolk District Medical Society were understood in the sense in which they were referred to in our columns by several of those who were present at the meeting and took part in the discussion. Notice would have been taken of Mr. Lee's remarks at the time, had he not left the room.—Ed.]

#### ANOTHER RENDERING OF THE GREEK MESSAGE.

ROXBURY, MASS, February 18, 1887.

MR. EDITOR,—I have waited two weeks, in vain, for a vernacular translation of the message upon "B's" slate, and so suggest, that, had he in his waiting-room the proper *necessaries* (labelled after the manner of the Boston and Albany Railroad, "men," "women?"), he would have saved his fee, and us all the trouble of translating the message.

Yours truly, U. V. M.

#### DOMESTIC DEVICE FOR NIPPLE SHIELDS.

HOLYOKE, February 12, 1887.

MR. EDITOR,—The old adage, that "there is no new thing under the sun," was prettily contradicted by one of my patients, who, suffering with fissured nipples—so sensitive and painful that their contact with any fabric or dressing caused intense distress—invented for herself most perfect nipple-shields, by suspending from a ribbon about the neck, two deep, wire tea-strainers.

They were held in place by a properly-fitting waist, and the nipples, thus covered, were entirely free from any irritation.

She had, moreover, such a copious supply of milk, that it was otherwise quite impossible to keep the nipples dry. This was remedied by the ready passage of the milk through the wire gauze to a layer of absorbent cotton covering the tea-strainer.

Not until she began to employ this method of protecting the nipples did the process of healing go on satisfactorily.

This young mother's clever device has been a source of great comfort in a number of similar cases which have since then come under my care.

I believe that this use of the tea-strainer is quite novel, and trust that its value may be tested by some of your readers.

Truly yours,  
FRANK HOLYOKE, M.D.

#### THE TRIALS OF AN ANATOMIST IN THE LAST CENTURY.

LEXINGTON, MASS., January 28th, 1887.

MR. EDITOR,—The following letter "to the impartial Publick," written in 1771, may be of some interest to physicians and pharmacists of the present day.

Yours respectfully,  
ROBERT M. LAWRENCE, M.D.

#### To the Impartial Publick:

It is with great reluctance I appear in print, but it is become necessary, as I have been represented to the Publick in an odious light by a set of men who cannot bear any should live but themselves. To set this affair in a clear light, it is proper to acquaint the Publick that about twelve months ago I set up an Apothecary's shop in Worcester, which was disagreeable to a certain number of men who would if possible monopolize (to themselves) all the Profits of the Town.

In this situation my conduct was narrowly inspected, and unfortunately for me, I gave them an opportunity by taking up the body of one Linsey, who was executed on the 25th of October last, with no other view than the advantage of having a skeleton in town, whereby other surgeons and myself might gain further knowledge of the human structure. At this they rejoiced, proclaiming that I had done for myself and that I must leave the town. I ought to be hanged, etc., till they enraged some people to such a degree that a number, after consulting lawyers to know if I had laid myself open to the law (resolving to prosecute me without mercy) finding I had not, they came

<sup>1</sup> From the Boston Gazette and Country Journal, Monday, February 18th, 1771.

in a riotous manner to my house, demanding the body, which I delivered; desiring that they would keep it covered. Instead of taking my advice (with a view to irritate the minds of the people) they exposed it the remainder of the day to as many as they could collect, which had the desired effect, so much that they surrounded my house soon after in the night, blowing horns, ringing bells, hanging up a dead b-tch before my door, etc. Notwithstanding all they did, the thinking part of the people considering ultimate design was to get knowledge which would tend to the publick good, my practice and custom returned as formerly. But being hitherto baffled in their attempts, they published an anonymous advertisement respecting me, as using the body in an inhuman manner and contrary to his desire. I can make oath I did not know his desire (it was known only to a few) till after the affair happened.

And that their advertisement might take the greatest effect, they inform you it is truth, and attested by five respectable gentlemen. These gentlemen I allow to be as worthy as any, and I believe the publick will think so when they are informed they were requested to sign the advertisement, but one and all refused, on account of its being a spiteful, ill-natured, malicious thing. Having represented the facts just and truly as they were, I leave it to the impartial Publick, whether or not I ought to be represented to the world in such an infamous manner, as these men and their dependants have done. After examining the whole with candor, I hope my friends and customers will see through their evil designs and continue their favours as usual.

I remain the Publick's most obedient humble servant,  
ELIJAH DIX, M.D.

## REPORTED MORTALITY FOR THE WEEK ENDING FEBRUARY 12, 1887.

Cities.	Estimated Population.	Reported Deaths in each.	Deaths under Five Years.	Percentage of Deaths from

Northampton	12,896	6	2	50.00	—	—	50.00	—

Deaths reported 2,544: under five years of age 1,017; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrhoeal diseases, whooping-cough, erysipelas and fevers) 435, acute lung diseases 404, consumption 385, diphtheria and croup 178, measles 85, typhoid fever 45, diarrhoeal diseases 44, scarlet fever 24, malaria fever 16, cerebro-spinal meningitis 11, erysipelas 11, whooping-cough 13, small-pox four, puerperal fever four. From diarrhoeal diseases, New York 16, New Orleans four, Philadelphia, Montreal, Providence and New Haven three each, Cleveland and Fall River two each, Brooklyn, Baltimore, Richmond, Charleston, Lowell, New Bedford, Chelsea, and Haverhill one each. From scarlet fever, New York 10, Brooklyn five, Philadelphia four, Pittsburgh two, Providence, Taunton, and Malden one each. From malarial fevers, New York six, Brooklyn three, Cleveland and District of Columbia, two each, Philadelphia, Baltimore and Buffalo one each. From cerebro-spinal meningitis, New York three, Lowell two, Philadelphia, Buffalo, Pittsburgh, Lynn, Springfield and Gloucester one each. From erysipelas, New York four, Philadelphia two, District of Columbia, Pittsburgh, New Haven, Haverhill,

and Malden one each. From whooping-cough, New York and Richmond four each, Philadelphia two, Buffalo, Montreal and Worcester one each. From small-pox, New York three, Brooklyn one. From puerperal fever, Boston two, Cleveland and Pittsburgh one each.

In the 32 cities and greater towns of Massachusetts, with a population of 1,027,994 (population of the State 1,941,465) the total death-rate for the week was 20.89 against 18.95 and 22.45 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 8,245,068, for the week ending January 31st the death-rate was 21.1. Deaths reported 3,734: infants under one year of age 781; acute diseases of the respiratory organs (London), 432; measles 130, whooping-cough 76, scarlet fever 54, diarrhoea 41, fever 37, diphtheria 33.

The death-rates ranged from 11.1 in Derby to 36.6 in Bristol; Birmingham 20.1; Bradford 19.8; Hull 19.1; Leeds 23.1; Leicester 19.3; Liverpool 26.1; London 19.6; Manchester 27.9; Nottingham 19.8; Portsmouth 22.7; Sheffield 19.6; In Edinburgh 18.8; Glasgow 29.8; Dublin 28.2.

The meteorological record for the week ending February 12, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending	Barom-eter.	Thermometer.				Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather.			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM FEBRUARY 12, 1887, TO FEBRUARY 18, 1887.

SMITH, JOS. R., lieutenant colonel and surgeon. Detailed, in addition to his present duties, as President of the Army Medical Board in New York City, N. Y. S. O. 38, A. G. O., February 15, 1887.

THREMAINE, W. S., major and surgeon. Sick leave still further extended four months, on surgeon's certificate of disability. S. O. 39, A. G. O., February 16, 1887.

WAKEMAN, WM. J., first lieutenant and assistant surgeon. Relieved from duty in Department of Platte, to take effect on the expiration of his present leave of absence, and ordered for duty at Fort Walla Walla, Wash. Ter. S. O. 36, A. G. O., February 12, 1887.

MORRIS, EDWARD A., first lieutenant and assistant surgeon. Leave of absence extended twenty days. S. O. 35, A. G. O., February 11, 1887.

HARRIS, H. S. T., first lieutenant and assistant surgeon. Ordered from Fort Clark, Tex., to Fort Ringgold, Tex. S. O. 16, Department of Texas, January 31, 1887.

McCURRY, GEO., captain and assistant surgeon. Granted leave of absence for one month, with permission to apply for one month's extension. S. O. 35, A. G. O., February 11, 1887.

TAYLOR, ARTHUR W., captain and assistant surgeon. Relieved from duty at Camp Medicine Butte, Wyo., and ordered for duty at Fort Laramie, Wyo. S. O. 14, Department of the Platte, February 12, 1887.

WYETH, M. C., captain and assistant surgeon. Ordered from Fort Wayne Mich., to Fort Barrancas, Fla. S. O. 39, A. G. O., February 16, 1887.

#### SOCIETY NOTICE.

SUFFOLK DISTRICT MEDICAL SOCIETY. SURGICAL SECTION.—There will be a meeting of this Section at 19 Boylston Place, Wednesday evening, March 24, at eight o'clock. The subject for the evening will be the "Treatment of Head Injuries." Dr. M. H. Richardson and Dr. E. H. Bradford will read papers. Dr. Morton Prince will illustrate the "Topographical Anatomy of the Brain on the Living Subject."

G. H. MONKS, M.D., Secretary.

#### OBITUARY. — FENNER HARRIS PECKHAM, M.D.

Dr. Fenner Harris Peckham, one of the oldest and best known physicians of Providence, R. I., died February 7th, of chronic Bright's disease, from which he had suffered for nine years. He was born in Killingly, Conn., January 27, 1820, and was the son of Dr. Hazard Peckham, an able and noted physician. After graduating at Yale Medical College in 1842, Dr. Peckham began his medical practice in Killingly, Conn. (now Putnam Heights), and removed to Providence in 1852. He was twice chosen president of the Rhode Island Medical Society. He has contributed to this JOURNAL and to literature several valuable addresses and monographs on special subjects of medical research. During the Civil War he served with distinction as a surgeon, first with Rhode Island regiments, and afterwards as surgeon of the board of enrollment of the second Rhode Island district. He leaves a wife and six children. To his only

son, Dr. F. H. Peckham, Jr., he relinquished the more arduous duties of his profession in 1878. One daughter, Dr. Grace Peckham, is an educated physician in successful practice in New York City.

TWO CASES OF CHRONIC ALCOHOLISM.<sup>1</sup>

BY W. A. GORTON, M.D.,  
Superintendent Danvers Lunatic Hospital.

Of the toxic neuroses, those produced by alcohol are probably among the most frequent, as they are certainly among the most interesting. So diverse have been the clinical phenomena attending their development, that until within a comparatively short period only a vague and general classification of them has been made, and it seems highly probable that many cases of nervous disorder have been erroneously attributed to other than alcoholic influences. The various forms of mental disorder produced by continued indulgence in the use of alcoholic drinks might be dwelt upon with some interest, and, perhaps, with profit, but the cases I have selected are chosen mainly to illustrate the complex character of what is generally called "Chronic Alcoholism."

A. H. J., male, aged thirty-four, married, native of United States, a milk-dealer by occupation, was admitted to the Danvers Lunatic Hospital, November 22, 1883. His friends stated that he had been a man of good bodily health and good mental capacity. Heredity good. For several years he had been very intemperate, and had indulged in venereal excesses. Seemed in perfect bodily health until August, 1882, or about fifteen months prior to admission, when he had what was called an attack of sciatica, which affected the right side principally, though pain was experienced on both sides, and which lasted about two months, confining him to bed most of this time. Experienced severe pain in his limbs during almost the whole period, but showed no mental symptoms. At the end of two months he had sufficiently recovered to resume his business and to renew his alcoholic and venereal indulgences. He continued in a condition which enabled him to attend to his work until July, 1883, although he suffered at times from neuralgic pains in his limbs. In July, 1883, or about three months before admission, he complained of being ill, suffered from the old pain in the limbs, but showed no special muscular weakness, although he fell from his wagon shortly before he gave up work. At this time he showed no mental symptoms that attracted the attention of his family, nor did he complain of any difficulty of hearing, vision or locomotion. He continued to drink to excess until August, when he began to show mental disturbance in the way of forgetfulness, incapacity for work and indifference to surroundings. At this time it was first noticed by the family that his gait was getting to be clumsy and unsteady. From this time until he entered the hospital he failed in all respects, becoming much demented and almost helpless from increasing feebleness of the lower limbs. He had no vesical or rectal paresis, and no fits. There was no direct history of syphilis. Examination on admission gave the following notes: man of medium height, well built but imperfectly nourished. Pupils are large in size, respond sluggishly. Tongue points to right and shows marked gross and fibrillary tremor. There is no appreciable lesion of heart or lungs, though the cardiac sounds are weak and the

pulse rapid, 144. Temperature normal. Is scarcely able to walk, gait showing extreme ataxia. Stands with eyes closed, but does so with extreme difficulty. Nutrition of limbs fair. The patellar reflex appears to be about normal on the left side, but is scarcely perceptible on the right. Cutaneous reflex apparently normal. Cutaneous sensibility apparently normal. Moves arms and uses hands without notable embarrassment. Speech incoherent, but articulation is not perceptibly impaired. Mentally is greatly confused, does not know where he is, cannot tell day of week or month. Seems greatly elated, but does not reveal delusions of grandeur. Mistakes identity of those about him. During the fortnight following his admission patient underwent no particular change. Was unable to walk without assistance, and passed much of the time in bed. Mental confusion persisted. Received no medicine. After this, patient began to improve, both mentally and physically, and two months after admission it is noted that he has become much clearer mentally, and is able to assist in ward work. Is childish in manner, memory is impaired and he has numerous delusions of identity. Says he feels well, has no pain, and thinks he ought to go home. Gait is slightly ataxic, but he gets about quite easily. In April, five months after admission, he had recovered almost completely from ataxic symptoms, and had gained greatly in general strength. Still showed delusions of identity, and thought he had discovered a new way to preserve meat and milk, which, when patented, would make his fortune. Improvement was progressive, and at the end of a year he had become able to do regular and hard work without fatigue, and had in great measure lost his delusions, though he was still uncertain about the identity of certain people about the hospital. Had had no neuralgic attack since admission. Fifteen months after admission he was discharged; has since remained well as far as is known, though I have not seen him for a year, but at that time he was in vigorous physical health and had no delusions.

The second case is that of a male, single, age thirty-five. A commercial traveler by occupation. Of good mental capacity and good physical health until he broke down from prolonged dissipation. Though very intemperate he had been able to support himself until the year preceding his admission, during which he was, for the most part, unable to work. In the spring of 1885 had reached such a state of mental, moral and physical degradation that he was placed in the Washingtonian Home for treatment, from which place he was transferred to the Danvers Lunatic Hospital, July 23, 1885, as a dipsomaniac. On admission he was found to be practically helpless from well-developed paresis of both lower extremities, and his condition indicated great physical prostration. Complete examination disclosed a large bed sore just above the left gluteal region, in the center of which was a large dark and offensive slough, and a smaller sore, apparently of more recent development, on the left knee. Was wholly unable to stand, but by great effort could partly flex the limbs. The cutaneous sensibility in both legs was found to be delayed but not markedly diminished. There was absence of the patellar reflex and of ankle clonus on both sides. Muscles of both limbs were flabby, and the general contour was indicative of atrophy. The respiration was accelerated and labored. Voice sounds weak and articulation difficult

<sup>1</sup> Read before the Boston Medico-Psychological Society, November 18, 1886.

and explosive in character. Incomplete paralysis of bladder and rectum. Was mildly delirious. Talked in a calm, self-satisfied way, but had many delusions of identity, and did not know where he was. Thought he would be all right if allowed to get up and dress himself and take a little exercise. Said he had been paralyzed once before from syphilis, which he contracted at the age of eighteen, seventeen years before admission. Pulse 98, temperature 98°. For a week there was no perceptible change in his condition. Was mildly delirious, restless, and troublesome. Began to complain of pains in his limbs, which were partly due to the bedsores, which involved the greater portion of the left gluteus maximus muscle, and partly to some other cause, which was thought to be possibly syphilitic and he was given K. I. gr. xv. t. i. d., with hypnotics and anodynes at night. At the end of a month he had undergone slight improvement, but was still in a state of great exhaustion. Had acquired a certain amount of power in the lower limbs, the respiratory embarrassment had diminished, the vesical and rectal paresis had disappeared, the cutaneous sensibility was no longer delayed, and the bedsores had commenced to heal. Still showed loss of memory, with the same fleeting delusions of identity. Begged almost constantly for whiskey, which he thought would at once restore him to the full possession of all his faculties. Had taken it pretty freely with egg and milk, from the time he was admitted. At this time he was given hydrarg. protiod., grs.  $\frac{1}{2}$  t. i. d. During the next month improvement was quite rapid, he had become able to walk, but his gait was unsteady, respiratory embarrassment had wholly abated, and he seemed rational and appreciative. Unfortunately no record of the condition of the patellar reflex was now made. On the 4th day of November, 1885, or nearly four months from the date of admission, he had apparently made a complete recovery. He declared that he felt as well as ever; and at any rate he was well enough to run away from the hospital and make good his way to Cambridge, since which time nothing has been heard from him. The decided paresis, the bad muscular nutrition, the acute bedsores, the delayed sensibility, and the rectal and vesical paresis, induced me to make the diagnosis of acute myelitis, but with the qualification that the case was one of chronic alcoholism, and that a long time must be allowed to elapse before a positive opinion could be given. I am aware that the syphilitic element of the case is not to be overlooked, but after a lapse of seventeen years, during which the patient declared he had taken mercury enough to sink him, it seemed a little less likely that syphilis was the cause of his trouble, than his continued indulgence in alcohol almost up to the commencement of the attack.

I am aware that the foregoing histories are incomplete in many respects, but they were made when the patient, owing to the great amount of mental disorder present, could give no assistance, and with no special reference to being used in subsequent reports. Similar cases have been numerous reported and diversely explained, but it seems to me that these two at least come within the descriptions of alcoholic neuritis and paralysis with which the German periodicals of the past year have been largely filled, a most excellent *résumé* of which, made by Dr. Knapp, may be found in the *Boston Medical and Surgical Journal* for September 16, 1886.

# THE APPEARANCE OF INTERMITTENT FEVER NEAR THE NEPONSET RIVER.<sup>1</sup>

BY J. S. GREENE, M.D., OF DORCHESTER, MASS.

WHEN the causes of disease are studied in the presence of a wide-spread epidemic, or where endemic phenomena prevail over a large territory, the abundance of material gives advantages too obvious to need particularising; yet this very abundance may prove a source of perplexity. It becomes necessary to recognize and estimate the power of counter-active or intensifying influences. Evidence collected from many and various sources has to be weighed and sifted. The value of the work depends much on the judgment as well as the industry of the worker; for he has both to collate and arrange facts and opinions, and to sum up his conclusions with judicial fairness.

Such, on intermittent fever, was preëminently the work of Holmes fifty years ago; and such are the quite recent papers on the same subject by the Drs. Adams. Far less ambitious is the mere reporter's work of describing those things only which his own eyes have seen; yet his few facts, in their very simplicity, may have some significance to justify their presentation. Such is my humble and easy task, and such my apology.

In a practice of twenty-three years I have not known a case of intermittent fever in Dorchester nor Milton, until within the last four years, *except such as have been imported* from malarial localities. Other physicians say that they have seen no indigenous cases. Dr. Benjamin Cushing remembers to have heard his uncle, Dr. Thaxter, say that he had one such case in Dorchester. Perhaps it would not be too sweeping a statement to say, that with barely an exception, the cases which I shall mention are the only instances of intermittent fever ever known to have had their origin on the soil of Dorchester or Milton. I have seen seven thorough-going cases in four different localities—two in Dorchester and two in Milton. Besides these I have seen two cases of uncertain etiology, which being each resident under one or other of the four roofs covering the undoubted cases, I suspect of partaking the infection. Dr. M. V. Pierce, of Milton, has lately seen a case.

I will now mention the several cases, and briefly describe the places where they occurred.

The first case was in September, 1882, in the person of a man whom I had known for years as a laborer in Milton, at the skin-shops, so called, where fleeces are washed. Here he had developed so characteristic a case of tertian intermittent that I formed a probable diagnosis from his aspect, as I saw him approaching my house. He was an Irishman, about thirty-five years of age, previously healthy and able-bodied. At the time of his attack he was living on the first floor of his house and his roof was leaky. Afterwards the roof was repaired, and he moved to the second floor.

This wool-yard forms part of a relatively low-lying level tract of seventy-five or a hundred acres extent, between Milton Hill and the elevated land to the westward, where stand the churches and public buildings of Milton. Through this intervalle flow the pure waters of Pine Tree Brook, which empties into the Neponset a short distance below the eastern bor-

<sup>1</sup>Read before the Boston Society for Medical Observation, December 6, 1886.

der of the tract. A fog often clings to this small plain while the air is clear on the hills around; and the passer, remarking this, might suspect the plain of insalubrity. But such suspicion would find no support in facts. Time out of mind this same interval has been the abode of healthy long-lived generations. The western breezes find it, while Milton Hill protects it from the fiercer north-east blasts. It has a gravelly soil, which is well drained by the brook before named. In all respects have the time-honored geoponic conditions in the wool-yard, through the brook valley, and throughout the town, remained substantially unmo- lested, with this one exception.

For about ten years past this brook has been dammed at its entrance to the wool-yard, and the meadow above flowed, to procure a winter's crop of ice. The brook, thus broadened into a pond, has not been set wholly free after the ice-harvest, but only in part; and throughout each summer there has remained some small semblance of a pond. The same brook has for twenty-five years been dammed a mile higher up; but there the gate has been wholly removed after the ice-harvest, and the brook restored to its ordinary channel.

My second case occurred the next following year, in July, 1883. Mrs. J. M., aged about thirty-three, married, previously healthy, occupying with her family, consisting of a husband and three children, half of a one-story, two-tenement house on Clapp Street, in rear of the First Parish Church of Milton, was taken with a well-developed case of tertian intermittent.

This house, as will hereinafter appear, has been the seat of other cases of the disease. Its rear and westerly sides lie close to the border of a five-acre lot of woodland, mostly of young growth. This lot has had, of late, no visible drainage, though the land is relatively high. The making of Thatcher Street, parallel with and south of Clapp Street, in 1877, without any culvert, has cut off the wood-lot in question, lying between the two streets, from its former drainage into the run, and it has standing-water on a portion of its surface during the cold season, though dry during the heat of summer.

October 15, 1884, case No. 3 appeared on the Dorchester side of the Neponset, in the person of a married woman, aged about thirty, occupying rooms in a house on the northwestern corner of a several acre tract sometimes called the Lava Beds. This is a tract badly drained, like that mentioned. Years ago it was a marshy meadow. It has gradually been partly filled in causeway fashion, and an open drain, not deep enough for thorough drainage, traverses it from north to south, crossing under River Street to the river. The western side of this tract is cut off from even this poor drain, by the completion, without any culvert, of a causeway or projected street from Sandford to River Street, north to south.

The house occupied by my patient stands on the westerly side of this causeway, and is therefore included in the portion thus cut off from drainage. The filling-up has been gradual during several years, and its effectual completion was perhaps celebrated, not unpunctually, by the appearance of this typical case of intermittent at its gate.

In July, 1885, a seven years' old daughter of Mrs. M., in the Clapp Street house, had a chill followed by fever, but under treatment a second paroxysm was prevented. In August following, a man of fifty years

and more, living in the other tenement of the same house, had a succession of violent paroxysms of the tertian type, characterized by urgent vomiting and prostration in the cold stage.

This man has had a recurrence this year, and his adult son, without chills or fever, has become weak, and has the aspect of one with malarial cachexia. He has tenderness over the region of the spleen. Another child of Mrs. M., three years old, has recently had an attack, also of the tertian type, making the fourth or more probably the fifth case in the same house.

This autumn, the 21st of October, a case presented itself on the southern border of Vose's Grove, in Dorchester, in a new house built close to the northwestern corner of the salt marsh overlooked by Milton Hill. The patient was a boy of three years, and the form of the disease was quotidian. Within a day or two of the beginning of his sickness, an infant of fourteen months, in the same family, died after an illness of several weeks' duration, dating from a blow of a stone against the upper lip. This was followed by abscess and necrosis of alveolar portion of bone. I did not see the babe until a day or two before death, and my diagnosis was pyæmia. The sequel suggests the inference that malarial poison was a factor in the case.

The house stands on the southerly slope of a sandy knoll only recently occupied for dwellings. This knoll is a low promontory, half surrounded by marsh, and the house in question stands within twenty feet of tide-water when high tides cover the marsh.

Ebb and flow is quite unobstructed here, for the rail-road, passing through the grove, runs to the northward of this knoll. The water of the well has a marshy taste and smell.

Dr. Pierce's recent case was a man employed on the coal wharf in Milton, opposite Vose's Grove. He slept in the office at the head of the wharf.

This completes my brief summary of cases and their surroundings.

Two of the localities implicated are at the head of tide-water and near the edge of marsh. The other three present, as the only perceived condition differing from surroundings of an earlier time, artificial obstruction by dam or causeway to the natural drainage of adjacent soil. In the two places where a plurality of cases is recorded, it is probable that the water of the wells in use is injuriously affected.

## REPORT ON PROGRESS IN THORACIC DISEASE.

BY FREDERICK C. SHATTUCK, M.D.

SYSTEMATIC MUSCULAR EXERCISE AND LIMITATION OF FLUIDS INGESTED AS THERAPEUTIC AGENTS IN CERTAIN CONDITIONS CHARACTERIZED BY CARDIAC INSUFFICIENCY.

It is more than fifty years since Corrigan advocated the restriction of liquids in cardiac failure; more than thirty years since Stokes, apropos of incipient fatty disease of the heart in relatively young subjects, wrote: "The symptoms of debility of the heart are often removable by a regulated course of gymnastics, or by pedestrian exercise, even in mountainous countries, such as Switzerland, or the highlands of Scotland or Ireland." These suggestions of two of the greatest Irish masters of medicine are likely

now to bring forth fruit more abundantly, thanks chiefly to the labors of Oertel, the third German edition of whose "Handbook of the General Treatment of Circulatory Disturbances" is before us.<sup>1</sup> We cannot but regard this work as marking an epoch in the treatment of certain conditions involving, and more or less characterized by, cardiac insufficiency. While it is impossible here to do more than attempt an imperfect sketch of Oertel's ideas and the manner in which he carries them out, we hope to do our part in calling the attention of our readers to the book, and commending it to their thoughtful study.

The introduction begins as follows: "When the hydrostatic equilibrium of the columns of fluid in the various systems of pipes in the human body is lost; when the amount of blood flowing to the heart is no longer in accurate correspondence with the amount flowing from the organ; when the pump fails to propel onward all the fluid delivered to it, and the fluid is, consequently, dammed back, disturbance of the circulation follows, which must entail serious results to the organism unless they are rectified in some way or other. The immediate causes which underlie these disturbances are to be found either in the pump itself, the heart-muscle, in weakness of its contractile, and hence, of its propulsive power; in imperfect closure of its valves and contraction of its orifices; or else in one or another of the systems of pipes which has been so encroached upon as to be no longer able to hold the amount of fluid which it should, to wit: in feebleness of the muscular structure of the heart, in fatty conditions of the heart and general obesity, in disease of the valves of the left side of the heart, mitral insufficiency, and mitral or aortic stenosis; also in curtailment of the pulmonary circulation, whether due to emphysema, chronic interstitial pneumonia and bronchiectasis, curvature of the spinal column, pressure from pleuritic effusions or thoracic tumors."

To select from these conditions that which will afford the most obvious illustration, let us take the fatty heart, combined with general obesity. Twenty-seven cases have undergone Oertel's treatment, all with brilliant success. The patient has long indulged in larger quantities of nourishment, and particularly of fluids (beer), than he needed to balance equally repair with waste. Thus fat has been abundantly, though gradually, deposited in the overflow basins, the skin and omentum, about the kidneys and heart. The more inconvenient exercise becomes, the more it is curtailed, ingestion going on the same. Fat is deposited between, or even in the bundles of the muscular fibres of the heart. All this time the blood-mass has been slowly increasing, and greater demands are made upon the heart than it is able to meet. Dyspnea follows the slightest exertion, attacks of palpitation are frequent, oedema appears in the legs, the skin of which may become more or less deeply pigmented as another result of the chronic venous stasis; the urine is diminished in quantity, and is albuminous. In short, the condition of the patient is deplorable, and palliation seems all that can be fairly expected of treatment. Oertel's cases show, however, that an actual cure may be wrought by an intelligent physician in an obedient and courageous patient.

The blood-mass must be reduced by great limitation

<sup>1</sup> The work constitutes the fourth volume of Ziemesen's "Handbook of General Therapeutics." The first three volumes have already appeared in an English translation, published by William Wood & Co.

in the amount of fluid and careful regulation of the solid ingesta; by systematic exercise, preferably on foot, in the open air, and in a hilly region, and, perhaps, by vapor-baths or pilocarpine. Exercise diminishes the blood-mass, of course, by favoring perspiration and the discharge of water through the lungs; but it also promotes oxidation and nutrition generally, that of the heart-muscle, as well as that of the other organs and tissues. Absorption of the fat takes place, and the newly-formed vessels belonging to it disappear. The hydrostatic equilibrium is gradually restored, and the patient, who, at first, was able to walk only a very short distance on a level without being arrested by urgent dyspnea, can take long walks, up and down hill, with ease, and is restored to activity and usefulness. Especially during the early part of the treatment, thirst is apt to be more or less painful; but its gratification must be resisted, and the symptom grows less and less prominent as the equilibrium is approached. Relapses are, of course, to be guarded against by the permanent avoidance of excesses.

A study of the cases of general obesity, with weak hearts presumably abundantly enveloped in fat, detailed by Oertel, shows clearly that neither dyspnea, cyanosis, nor oedema, are contra-indications to muscular exercise. He reports, also, twenty-four cases widely varying in many respects, but all involving more or less serious and permanent organic changes, and all presenting the common features of impaired cardiac compensation and loss of hydrostatic equilibrium. The consideration of these cases forces the question upon us whether physicians generally do not inculcate rest in some cases of cardiac debility, where exercise, carefully graduated and carried out, is really indicated? Special emphasis is to be laid on the word *some*. We are fully alive to the vital importance of rest, as a general principle, in the treatment of heart disease. We know only too well that to err is human, and that it is, on the whole, wiser to err on the safe side. Still we must be constantly on our guard against the danger of putting our patients into the Procrustean bed of a general principle. The manner of life of the Germans, especially as regards the consumption of beer, favors the development of a larger number of those cases in which Oertel's treatment scores its most brilliant successes than does our manner of life and climate. Valvular disease, with imperfect compensation, is, however, equally common, and we repeat that, in some of these cases, we are convinced the principle of rest may be, and is, sometimes, carried too far.

The case of the late Lord Iddesleigh is one somewhat in point. For years he led a restricted life, in accordance with the advice of his physicians, on account of mitral disease; in 1855 he determined to disregard the advice, and for thirty years was in the thick of English political life, part of the time as a cabinet minister and leader in the House of Commons, finally dying at the age of nearly seventy. The lesson to be brought home to us in this is the importance of a careful study of each individual case coming under our care, and of a wise adaptation of our physiological, pathological, and therapeutic knowledge to the requirements of that case, considered, as far as is possible, as an individual, rather than simply as one of a class.

In closing, it may be of interest to mention that Case I, reported by Oertel at great length, is said to be that of the author himself, who, contrary to the adage, did not have a fool for his patient.

## THE PNEUMATIC CABINET IN PULMONARY DISEASES.

The aro-therapeutics of lung disease has never received anything like the attention in this country and in England which has been devoted to it on the continent of Europe, and especially in Germany. The invention and introduction of the pneumatic cabinet of Williams and Ketchum has stimulated experiment and research in this direction, and the medical periodicals have, in the last two years, contained many articles on the theory and practical application of the apparatus. I have purposely refrained from any mention of it in these reports up to the present time, in order that results rather than hopes of results might be dwelt upon. It is, of course, still too early for the formation of positive conclusions; but something is to be learnt from the reports which have come in. In the first place, a few words as to what the cabinet is and the claims of its projectors. We can then see how far those claims have been justified.

In using the apparatus of Waldenburg and its modifications, the patient, exposed to the ordinary atmospheric pressure, inspires compressed or expires into rarefied air. In the cabinet the patient is exposed at will to increased or diminished pressure, but breathes from and into air at the ordinary pressure. Pulmonary gymnastics are therefore a common feature of the two systems, and the benefits which are to be derived from increased dilatation and ventilation of the lungs are obtainable from either; whether these benefits are obtainable in equal degree from both systems we do not propose to consider.

The peculiar advantage which is claimed for the cabinet lies in the alleged facility with which, by its aid, medicated sprays can be thrown into the lungs, and compelled to condense within the minute air spaces. Mr. Ketchum, in a short paper on "The Theory of the Pneumatic Cabinet," says, "topical medication was the goal toward which the projectors devoted their energies," a goal which the discovery of the bacillus tuberculosis, like a telescope, brings more clearly into view.

Dr. V. Y. Bowditch,<sup>2</sup> who during ten months treated twenty-seven cases of various pulmonary diseases with the cabinet, says: "My opinion, then, of the pneumatic cabinet, may be thus briefly stated: that, although in my hands it has not accomplished, perhaps, all I had been led to hope, yet I still feel that it has, at least, shown itself to be a valuable aid to us in pulmonary therapeutics, and I look with hope to see what it can accomplish in the future."

Dr. Sidney A. Fox, of Brooklyn,<sup>3</sup> has treated sixty-nine cases, thirty-four of which were phthisis: seventeen of them improved, ten showed no gain, and seven died. He writes cautiously and fairly, and is evidently encouraged to persevere in the use of the apparatus. "Over and over again have patients said to me, after having been told that they could not be cured, 'Doctor, I would like to continue the treatment because it makes me feel better, and you do not know what a relief it is to be able to take a deep breath.' It is a point worthy of emphasis that patients to whom cod-liver oil had been intolerable have taken it without difficulty when exhibited in conjunction with this special method of local treatment."

Dr. Westbrook<sup>4</sup> says, "In regard to phthisis pulmo-

nalis: I believe that in the early stages of the disease the cabinet is capable of doing much good, and in many cases by arresting the morbid process."

Dr. Platt,<sup>5</sup> who was associated with Dr. Westbrook in using the cabinet, believes its main action to be, the air about the patient being rarefied, a reduction of pulmonary congestion. He says: "time and time again patients have come into the office complaining of the sputa being blood-streaked, and, almost without a single exception, the use of the cabinet has relieved the symptoms in the course of a few minutes." It may be stated here that all the reports show there is no danger of hæmorrhage being excited when the cabinet is used in the ordinary way—the air contained in it being rarefied.

Dr. A. S. Houghton,<sup>6</sup> of Chicago, reports on thirty four cases, twenty-five of which were phthisis in one or another stage. His conclusions are as follows:

"(1) Pneumatic differentiation is of undoubted service in all conditions of primary infiltration.

"(2) When the febrile movement has been unchecked for many weeks before treatment, improvement, if any, will show itself within the first ten or twelve applications; if there is no abatement of symptoms its continuance is of questionable utility, and it may be absolutely contra-indicated.

"(3) That phthisical disease at the apices is more favorably treated than when at the base of the lungs.

"(4) That it is possible by this means to more thoroughly medicate the lungs than by any other known method.

"(5) That the expansion of the lungs by differentiation is itself a therapeutic measure of great merit.

"(6) The peri-and-inter-vesicular exudation is capable of cure by this method, and even third stage phthisis is benefited, at least temporarily."

Dr. Herbert F. Williams, of Brooklyn, one of the projectors of the cabinet, furnished the first report as to its clinical use.<sup>7</sup> A more recent article by him gives a list of all reports up to the spring of 1886.<sup>8</sup> Of seven cases of phthisis classed as recovered in the first report, five had remained well without further treatment, for a space of nearly ten years.

It will thus be seen that those who have put the cabinet to practical use are unanimous in the opinion that it is of service as a means of exercising the muscles of respiration, expanding the lungs, promoting the absorption of diseased products, and diminishing congestion. They all appear to think, also, that by its aid medicaments in the form of spray can be applied to the mucous membrane of the upper air passages, and perhaps the larger bronchi. With regard to the possibility of topical medication of the air vesicles, however, "the goal toward which the projectors devoted their energies," we do not meet with so much unanimity. Dr. Williams tells us that the toxic effects of quinine, atropia, and mercury have been obtained by the use of the spray; but this does not prove that the air vesicles were reached. Deeper conviction is carried by an experiment he performed on a rabbit, inserting a tube in the trachea through which a spray containing China ink was directed; after ten minutes the animal was killed and the ink was found in the alveoli and sub-pleural spaces. Of course, in the human sub-

ject much of the spray is arrested between the mouth and the upper part of the trachea.

Drs. Westbrook, Platt, and V. Y. Bowditch are all extremely skeptical as to the possibility of condensing a spray within the alveoli, and think that even if such penetration is secured the amount of medicament there deposited must be far too small to exert any germicidal effect, to say the least.

Our readers shall be kept informed as to the results of more extended use of the cabinet. No one will question the desirability of finding more efficient methods of combating a disease so common and so deadly as pulmonary tuberculosis.

#### THE BACILLI OF TUBERCULOSIS: THEIR ABUNDANCE IN SPUTUM WITH REFERENCE TO PROGNOSIS.

May<sup>9</sup> has made weekly examinations of the sputum of one hundred and thirty-nine tubercular patients in all stages of the disease, counting the bacilli in the preparations from each patient. The weight of the patients was also noted, and it was observed that decrease in the number of bacilli appeared much later than gain in weight; indeed, in many cases the bacilli increased in number at first, without any other unfavorable symptoms or signs. In two cases the number of bacilli decreased shortly before death, and in two others the organisms disappeared completely while the patients were losing weight and doing badly.

May consequently concludes that we can be sure of a loss of the power of vigorous growth on the part of bacilli in the lungs, only when, during months of observation, they gradually decrease in number—although a temporary increase may take place from time to time—and simultaneously the bodily weight and general conditions are improving.

#### PLEURISY ONLY A SYMPTOM.

Those of our readers who have studied in Germany must have all been struck with the doctrine there so generally held, that simple primary pleurisy is a very rare affection. This view is not so widespread in France, but has there adherents. Germain Sée, for instance, classes pleurisy among the infectious diseases. Landouzy<sup>10</sup> reports two cases confirmatory of this view, and formulates his opinion on the question as follows:

"(1) All demonstration is wanting of the dependence of acute primary pleurisy with effusion on exposure to cold, as is so commonly held.

"(2) Pleurisy attributed to exposure to cold is not a disease, like pneumonia, by the side of which nosogroups persist in placing it, but simply a morbid, and always secondary condition.

"(3) Pleurisy, whether acute in onset and characterized by large effusion, or local, subacute, or chronic, is a symptom of disease.

"(4) Without absolutely denying the occurrence of pleurisy as due simply to exposure to cold, I believe it to be most exceptional, as rare as it is thought to be common.

"(5) The part played by exposure to cold is, in pleurisy, as in erysipelas, pneumonia and zoster, quite subordinate: the true etiological factor lies in a cause which was latent until the day when the exposure took place.

"(6) This genuine etiological factor, this determin-

<sup>9</sup> Münch. Med. Wochschr., 1886. No. 25. Fortschritte der Medizin, 1887, p. 567.

<sup>10</sup> Revue de Médecin, July 10th, 1886.

ing cause is tuberculosis, often masked by the pleural effusion, and thus escaping recognition."

He goes on to say, further: "Any patient with pleuritic effusion is tuberculous, let him be vigorous, young, robust, and fat as you please; let him declare himself otherwise perfectly well and quite free from hereditary or acquired predisposition, unless the pleurisy can be attributed to an infection, (scarlet fever, puerperal fever, etc.), a dyscrasia (rheumatism), or a trauma (fractured rib, infarction)."

If this doctrine be true, all we can say is that tuberculosis is recovered from more frequently than has been supposed.

#### ACUTE PNEUMONIA IN UTERO.

Dr. Strachan<sup>11</sup> of Kingston, Jamaica, writes as follows: A patient, Nancy M., was admitted into the hospital under my care in December last, suffering from acute pneumonia (whole of left lung), and a history of illness covering the four days previous to admission. She was eight months pregnant. On the evening of the day of admission, her temperature was 103.6°, and she was delivered of a female infant. The infant died in less than twenty-four hours after birth with symptoms of acute pneumonia. A post-mortem examination showed acute pneumonic consolidation of the whole of the left lung. The mother made a good and rapid recovery.

[We do not remember having met with such another case in literature. It is to be hoped that the profession will be on the lookout for them in future, and endeavor to obtain autopsies on viable children born during an attack of pneumonia in the mother, but soon after succumbing. The transmission of the disease to the fetus proves conclusively that pneumonia is a general disease and not, as was so long and so universally held, a local inflammation.—REP.]

## Clinical Memorandum.

### TETANUS FOLLOWING ABORTION.

BY HOWLAND HOLMES, M.D., OF LEXINGTON, MASS.

I WAS rusty in the literature of tetanus, so far as to have no recollection that it ever followed child-birth or abortion as a cause, till it was forced upon my notice by the following case:

Mrs. M. was the mother of four living children, the youngest being thirteen months old. I attended her in her last two labors, which were quick and easy. They were preceded by a miscarriage between the births of the second and third child. About one o'clock on Monday morning of December 13, 1886, I was called to see her. She had had a quick miscarriage a few hours previous, of a four months' fetus, but the placenta had not come. It was not easy to deliver it without ether, and as the patient was averse to taking it and had ceased to flow, after losing an average amount of blood, I administered Flu. Ext. Ergot 3i, and left.

I saw patient again in the middle of the forenoon, and removed the placenta from the cervix uteri. With tepid water mildly carbolyzed, I syringed the womb, and enjoined on patient to syringe vagina every morn-

<sup>11</sup> British Medical Journal, 1886, p. 860.

ing with warm, carbolized water. There was no further pain or discharge, with the exception of a final fragment of placenta, Wednesday morning.

I saw her several times in the course of the week, and at my visit on Saturday, I found her so far recovered that my further attendance seemed unnecessary. She had had that morning free action from a dose of castor oil taken for slight headache, and was then anxious to know what her "bill of fare" might be.

The following Monday (December 20th), in the afternoon I was desired to see her quickly—"she could not open her mouth." Examination showed she could not part her teeth to admit a knife-blade or spoon-handle, the muscles of her face and neck were stiff and painful. She said two defective teeth had grumbled somewhat during the last few weeks, and possibly she had taken a little cold, to cause neuralgia from them. She had slept sweetly the night before, (Sunday night), had the best night's sleep she had had since she aborted. She had slept fairly Saturday night, and thought she should relish a piece of broiled steak for breakfast, but on making an attempt to eat it, she first found she could not fully open her mouth, and next that the process of mastication caused so much pain and discomfort that she was obliged to desist.

From that time her jaws became more and more clinched, and the muscles of the face and neck became more and more stiff and painful, till she and her husband lost confidence in her neuralgic theory and sent for me. I tried to believe it was neuralgia, but a horrid misgiving seized me. However, I tried to calm her fears, and prescribed volatile liniment.

She was worse at ten o'clock p.m., and I was again called. I had no longer any doubt I had tetanus to contend with, and asked for a consultation. At 11.30 p.m., a neighboring physician saw the patient with me, and after a thorough examination, reluctantly conceded that it might be a case of tetanus, but, like myself, he could not recall that it ever followed such a cause: Treatment was a continuation of morphine in  $\frac{1}{4}$  grain doses that I had commenced. We left her at 1 o'clock a.m., to meet again at 2 o'clock p.m., (Tuesday 21st). I saw her between 8 and 9 o'clock, that morning, finding her without improvement, and consultant saw her with me soon after 2 o'clock p.m. There had been some opisthotonos for twenty-four hours, and pain darted through from the sternum to the spine, extending down the shoulder blades, nearly the whole length of the back. From the first there was no tenderness in her bowels, but they were soft, flat, and natural, and, as they had been so thoroughly evacuated the previous Saturday, no effort was made in that direction. She passed water freely and with ease. Her mind was clear, and she was as calm and placid as her manner always was. By a forced effort she could part her teeth nearly a fourth of an inch on this day, but she sips but a few teaspoonfuls of milk or beef tea. Ether was given her, but the relaxed condition of the muscles of the neck and body only lasted while the influence of ether lasted. We gave nourishment, opiates and stimulants freely, but the patient died about 3 o'clock a.m., Wednesday, December 22d.

Professor Simpson, of Edinburgh, maintains that traumatic tetanus sometimes supervenes as a secondary obstetrical disease; regarding the interior of the

uterus, after abortion and parturition, as in a state of lesion similar to that of a wound on the external parts of the body.

## New Instruments.

### IMPROVED NON-OBSTRUCTING CANULA.

BY JOHN S. MILLER, M.D.,  
Assistant, Surgical Clinic, Jefferson Medical College.

THE frequent occlusion of the canula by intestine or omentum in the operation of tapping, has suggested the device shown in the cut. The stoppage generally occurs when about a pint of fluid has been withdrawn; and various manoeuvres are resorted to, such as the endeavor to float away the obstruction by changing the patient's position; or the dangerous one of introducing a probe through the canula, and generally without success.

The device to which reference has been made is a smaller and longer canula, introduced into that already in position, in case there is a cessation of flow. It is blunt, and provided with two long fenestræ. In the latter are springs, which expand and push away the obstruction on emerging from the original canula, and which are so solidly soldered as to offer no danger of breaking off in the abdominal cavity.

In reply to the query whether or not the gut can become incarcerated and wounded in the springs, it may be stated that, in several operations, no such accident has occurred, nor were efforts successful to bring such about upon the recent cadaver.

The instrument can be used with any trocar and canula above calibre No. 16, French. The instrument is manufactured by Charles Leutz & Sons, No. 18, North Eleventh Street, Philadelphia.

## Reports of Societies.

### PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

MEETING December 6, 1886, Dr. DE BLOIS in the chair.

Dr. J. S. GREENE read a paper upon

THE APPEARANCE OF INTERMITTENT FEVER NEAR THE NEPONSET RIVER.<sup>1</sup>

Dr. HENRY I. BOWDITCH showed a rough copy of a map of a part of Chelsea, Mass., and gave a brief abstract of a report made by himself and the late Drs. John Ware and Ephraim Buck to the Suffolk District Medical Society, and which the Society ordered to be printed.<sup>2</sup>

<sup>1</sup> See page 202 of this number of the Journal.

<sup>2</sup> Boston Medical and Surgical Journal, January 26, 1883.

By said report was demonstrated the fact that four cases of apparently genuine intermittent fever had originated in houses built on land that had been shut from the salt water near the mouth of the Mystic River. This was brought about by the erection of a dam in 1789, for the purpose of reducing the territory to a good arable condition, instead of marsh land, as it had always been. The project was a failure. The territories thus cut off contained two hundred and seventy-five acres, and the town of Chelsea rests, in part, now upon it. In 1816 the Company opened again the gates of the dam, and the territory was again, but less perfectly than before, covered by the incoming tide, and left bare with its outflowing. This continued till 1845, when the Winnisimmet Company again shut the gates, and determined to use the land for building homesteads thereupon. The old windings of the marshes were left exposed. Pools of water still continued, varying from two or three inches to two feet in depth, while the sloping borders were of a hard-baked clay, covered, at times, with dead mollusks or sparse and thin grass. There was no offensive odor perceptible. Several fresh-water springs continued, one of which was not lower than 54° F. during the year. Within two years after this second closure of the dam, four cases of true intermittent fever were seen and attended by seven physicians resident in Malden, Chelsea, and Boston.

Finally, Dr. Bowditch alluded to a fact related in the journal of the Rev. Noadiah Russell, tutor in Harvard College, in 1682, in which he states that he had been attacked by the disease; and in 1683 he states that it had been very prevalent and fatal, all indicating that, formerly, Eastern Massachusetts suffered from it much more than it has suffered during the past century.

DR. BUCKINGHAM stated that he had recently seen three cases in his service at the City Hospital. Two of these patients lived on the same street, near the Roxbury line; the third was a child, living near the other two, and who had never been far from this locality.

DR. V. Y. BOWDITCH called the attention of the Society to the statements made by Crudeli, in his address before the International Congress at Copenhagen, embodying the results of his long study of malaria in Italy, that while a certain amount of moisture was necessary for the development of the fever, yet it is by no means confined to swampy, low regions, but is often met in comparatively high lands. Dr. Bowditch alluded to the case of intermittent fever which had occurred in the village of Elizabethtown, high up in the Adirondack Mountains, and had been reported to him by one of the physicians of that place. The speaker could not state absolutely that the patient had never lived elsewhere, but from the manner in which the case had been reported to him, he had understood it as having developed there.

DR. WHITNEY thought that it was an important matter to have these isolated epidemics thoroughly investigated by the Boards of Health, especially with reference to the presence of microorganisms in the blood of those affected.

DR. F. W. JOHNSON said that he had recently attended a case of remittent fever in a gentleman who had never lived elsewhere than in Boston. The case terminated fatally. His diagnosis was confirmed by a consultation.

DR. FOLSOM had observed that many cases occur in

comparatively elevated localities. In a small town in the western part of the State, all the cases were on the top of a hill. The conditions of low land and moisture are certainly *favoring*, but not the only conditions. So far, there have occurred over one thousand cases in this State. Before the disease had so definitely followed up the rivers, there were a number of cases among the students at Williamstown; but, tracing these up, it was found that all the students had formerly lived in a very malarial locality in Staten Island. It was the speaker's experience that persons living for a time in a well-developed malarial region might remain free from the disease, and then have it manifest itself after a year's residence in another place.

DR. WADSWORTH mentioned a case of malarial fever of a very severe type, which was contracted by a brief visit South, during the war, and did not appear for a year or more after the return North.

DR. DE BLOIS had had under his care a young woman of Dorchester, who developed the disease in quotidian form, which persisted for a long time after changing her residence to New Hampshire. The only thing that accounted for the disease was that the cellar of the house in which she slept was very wet. Dr. De Blois said, also, that the fact was well recognized, in the West Indies, that moving the soldiers from the barracks, up the mountains, three or four hundred feet, entirely prevented the development of the disease.

DR. FOLSOM said that the late Dr. Holmes, of Milton, had reported to him the case of a lady who had the fever while living at the South, where she married. Coming North to live, she never had any sign of the disease; but her daughter, born shortly after coming here, when a few months old, had it severely. There could be no question as to the correctness of the diagnosis.

DR. GREENE, in closing the discussion, said that he had, in the paper of the evening, considered only those cases which had originated in that locality. He had seen other cases in the town, but their origin was elsewhere. He mentioned the case of two young ladies just home from a boarding-school in Providence, one of whom had spent one day and one night in Philadelphia, and the other had made a brief visit near Providence, in a locality where the first cases in that State originated. Both of these ladies had the fever, but neither then nor subsequently were there any cases at their boarding-school.

DR. J. J. PUTNAM read a paper upon

#### CHRONIC LEAD-POISONING.<sup>2</sup>

DR. BOWDITCH said that a case had come under his observation, where the only discoverable source of the lead was the solder used in kettles in which the water was boiled.

DR. WADSWORTH mentioned a case of simple optic atrophy occurring in a painter, in consequence of lead-poisoning. Except this lesion, there were almost no other symptoms pointing to this source. He had slight numbness of the hands and rheumatism of the left shoulder. The tendon reflex was not altered. Within a year he had seen a case of optic neuritis, with paralysis of the muscles, from lead.

DR. SABINE inquired as to the length of time after which it was possible to detect lead after the drinking-water was changed.

<sup>2</sup> Publication deferred.

Dr. PUTNAM said that it depended upon treatment. As the lead forms an insoluble albumenate with the tissues, it may remain a long time unless eliminated by iodide. In one case there had been a space of over ten months.

Dr. SABINE said that he questioned if the introduction of water-meters would not increase the danger of lead-poisoning, as people, to economize, would not allow the water to run and clear the pipes.

Dr. FOLSOM said that this class of cases, when simple anæmia and obscure nervous symptoms are caused by lead-poisoning, instead of the typical symptoms, are deserving of most thorough investigation. Sometimes its influence is shown by peripheral neuritis, sometimes by myelitis. The speaker said that pure Cochituate water passing through lead-pipes was devoid of danger, as it is so free from soluble nitrates, but since the introduction of Sudbury River into our supply this security has vanished. There requires to be the greatest caution and experience in analysis for lead, and unless one can be sure of these points, results are always doubtful. The speaker also desired to emphasize the caution, that the ordinary period during which iodide is given is entirely insufficient to break up and eliminate the lead, and instanced a case in illustration.

Dr. WEBBER reported the case of a woman who had lead symptoms, and the source of the poisoning was traced to the hot-water pipes from which the cook filled the kettle in the morning. One case, still under observation, had been using iodide for more than two years, and lead still is present in the urine. In several cases he has observed loss of the tendon reflex, but not in all. The speaker questioned in certain cases presenting cerebral symptoms, such as loss of mental power, inability to fix the mind, headache, and so on, how much was due to cachexia, or how much to lead deposited in the brain. In one case of complete paraplegia, with lead in the urine, after making a decided improvement, the patient died.

Dr. WADSWORTH spoke of the effects of lead-poisoning upon the eye.

Dr. PUTNAM inquired as to whether rubber work was to be included among the dangerous occupations. He had had a number of cases.

Dr. WEBBER said that he had also had several cases.

Dr. PUTNAM, in reply to an inquiry, said that large quantities of litharge were used in the preparation of rubber.

#### BOSTON MEDICO-PSYCHOLOGICAL SOCIETY.

PHILIP C. JORDAN KNAPP, M.D., SECRETARY.

NOVEMBER 18, 1886, DR. H. R. STEDMAN in the chair.

Dr. W. A. GORTON read a paper entitled

##### TWO CASES OF CHRONIC ALCOHOLISM.<sup>1</sup>

Dr. BOLAND spoke of a case at the Boston Lunatic Hospital, where a fireman, addicted to alcohol and exposed to cold and wet, had an attack resembling acute mania. On recovery, he suffered greatly from shooting pains in the legs. He was treated with faradism, and made a complete recovery. No diagnosis was made at the time, but, on looking back at the case, it seemed like neuritis.

Dr. LANE said that he saw many cases of alcoholism,

<sup>1</sup> See this Journal, page 201.

but little neuritis. He asked if these patients had the characteristic delirium.

Dr. GORTON said that they had not. One man thought that he would be all right if he could get up. Delusions of identity were common to both. In answer to Dr. Channing, he said that there were seven or eight similar, but less pronounced cases at Danvers. Five of them had some ataxia. The patellar reflex was seldom wholly gone, and they seldom had lancinating pains. Most of them recovered more or less completely. The second case was hardly a true myelitis, but it had all the symptoms of myelitis, except that the temperature was low. The patient had some irregular elevations of temperature, due, perhaps, to his bedsores. The first case came under observation a week after giving up alcohol, the second two or three weeks after.

Dr. CHANNING said that it was curious to find that the disease could be so far advanced while the patient remained outside of an institution. In the second case syphilis may have had some influence, but it is a question whether it would still modify the symptoms after seventeen or eighteen years. He had, however, recently seen a case where the only explanation was syphilis incurred fifteen years before. The patient could not take large doses of anti-syphilitic remedies. He asked if there were many dipsomaniacs at Danvers.

Dr. GORTON said that he had had sixteen in the last year. He tried to keep them sober, but otherwise he could do but little. The periods were usually short, and the friends, who were very annoying, asked for their discharge in from one to seven days after admission. The patient is apt to do as well in a week after getting sober as he is in six months; but, with many cases, it is useless to commit them, as they "celebrate" as soon as they get out. Before the law was passed, he used to get chiefly cases of delirium tremens. The present law says that the patient shall be otherwise of good repute, but this was sometimes disregarded.

Dr. J. B. AYER said that the greatest benefit he had seen in any case of alcoholism was in a man who was put on a farm, a long way off, but he now has an occasional spree. He asked what was Dr. Gorton's treatment of delirium tremens.

Dr. GORTON said that bromide and chloral did as well as anything. Chloral was pretty safe, although he had seen death follow a dose of fifteen grains in a patient with fatty heart.

Dr. AYER thought it well to add something to the bromide and chloral, to avoid the depressing effect; coca, however, causes wakefulness. He asked if Dr. Gorton broke off the use of alcohol at once.

Dr. GORTON said that he did except in the restless, typhoidal state, where milk-punch was given freely. Dr. James P. White, of New York, used to control jactitation, restlessness, and discomfort, by half a drachm to a drachm of tincture of lupuline, in addition to bromide and chloral. Coca was little used; in melancholia, patients sleep less well after it.

Dr. CHANNING said that he had tried hyoseyama in two or three cases some years ago, but, at first, it had a bad, exciting action, and later it was depressing, the pulse becoming weak and rapid.

Dr. BOLAND said that bromide and chloral were given at the House of Correction *pro re nata*. They also gave a drachm of a mixture containing twenty minims each of the tinctures of digitalis, hops, and capsicum.

DR. AYER said that large doses of digitalis were now abandoned.

DR. KNAFF said that he had seen digitalis used in doses of one to three drachms without any apparent ill effect. He had taken full doses of coca himself, in order to produce wakefulness, but without the slightest effect; idiosyncrasy, however, might have some influence, as strong coffee never had any effect on him. In his experience, alcoholic neuritis was quite a common disease. Beside the degeneration in the peripheral nerves, some investigators had also found changes in the cortex cerebri. In a number of cases he had seen the characteristic delusion described by Dreschfeld. The patients, who were unable to stand, would tell long stories of visits made that day to distant places, and give details of the people they saw and the conversations they held. They were also very lachrymose and hysterical. He was disposed to doubt the diagnosis of myelitis in Dr. Gorton's second case, as the patient recovered. In a number of cases of alcoholic neuritis, where the mental disturbance was marked, he had seen incontinence of urine; and, in a case of multiple neuritis with no alcoholic history, due perhaps to exposure, which he had seen in the summer, there had been a small bed sore. In some cases of alcoholic neuritis, the mental impairment, the ataxia, and the fibrillary tremor of the face and tongue, were such as greatly to resemble general paralysis; in fact, the French speak of a pseudo-general paralysis of alcoholic subjects.

DR. STEDMAN said that the resemblance to a general paralysis—seen, for instance, in Dr. Gorton's first case—was interesting. In some cases reported the resemblance was very marked, the patients having unequal pupils, ataxic gait, ambitious delirium, etc. The only point of distinction was that the alcoholic cases did not have the characteristic disturbances of speech. Large doses of digitalis were not mentioned now, as they had proved too dangerous. He asked if the reader found many cases of the true disease, dipsomania, not mixed with habitual drunkenness, as a result of depravity.

DR. GORTON said that the cases were hard to distinguish. He had seen one case of dipsomania—a capable man, with every desire to lead a proper life, who had a sudden, inordinate, irresistible craving for drink. He would begin to drink, and keep on until everything had gone; then he would be filled with intense remorse, and would contemplate suicide. He had had two attacks of delirium tremens. He would get better, stay all right for a number of months, and then go on another spree. For a time he worked hard in a gravel-pit, and did not indulge; then he went to Salem, and broke down again. He had no taste or appetite for liquor; it was a solitary habit with him, and the only satisfaction he got from it was to gratify his craving. Other cases—and these make up the bulk of the cases seen—go off on a spree to have a "good time with the boys."

—The population of France, by the census of May last, whose data are just published, shows a population of but 38,218,000, about 10,000,000 less than Germany. The increase for the last five years was but 540,000, against 770,000 in the preceding given quinquennium. The diminution is said to be due to Malthusian principles.

## NEW YORK COUNTY MEDICAL ASSOCIATION.

ANNUAL meeting, January 17, 1887.

After the annual reports of the Executive Committee and of the Treasurer had been read, DR. HERMAN M. BIGGS read a paper on the

### HISTORY OF AN EPIDEMIC OF DYSENTERY AT THE ALMSHOUSE, BLACKWELL'S ISLAND, NEW YORK.

In the years 1884 and 1885 there was some dysentery in this institution, though not of an epidemic character; but an examination made by an inspector of the New York Board of Health showed the sanitary condition of the buildings to be good. Some closets, which were undoubtedly the cause of the trouble, were not, however, inspected, as they were somewhat separated from the other buildings, and did not attract attention.

The epidemic in question commenced early in June, 1886, and the cases increased in number and severity until the 15th of July, when Dr. Biggs went on duty. At this time, from twelve to fifteen new cases of severe dysentery appeared each week in the female almshouse, and the weekly number of deaths from the disease amounted to five or six. Believing, as he does, that dysentery in the vast majority of cases is an infectious disease, due to some definite determinable cause, he immediately made a careful inspection of all the buildings in the institution, as well as of the food and water supplied to the inmates; examining thoroughly into all the conditions which might possibly bear upon the development of the disease. Aside from the element of over-crowding, nothing could be found to which importance could be attached as regards the causation of the epidemic, with the exception of one water-closet, in general use by the female inmates. This was separated from the main building by a road-way, and had a large cemented brick vault, with a sewer about one foot in diameter, leading from it to the river below, which was found to be in an exceedingly bad state. On entering the door the stench from it was so strong as to be almost intolerable. The vault was flushed by the water from the bath-house, which is in the same enclosure, and by rain-water from the roof of the main building. At the time of the examination the vault contained two or three feet of semi-solid fecal matter. During the early part of the summer the weather had been very dry; so that the supply of water from either source was very small. As far as could be learned, the closet had not been cleaned since the autumn of the preceding year, and it was ascertained that the outlet into the sewer mentioned was eighteen inches above the lowest portion of the bottom of the vault, which was round. Moreover, the sewer was found to be partly stopped up; and when it was remembered that the closet was in constant use by nearly eight hundred persons, some idea could be gained of the conditions prevailing at the time.

At Dr. Biggs's request, the closet was immediately washed out and disinfected. At the same time orders were given for the careful disinfection of all beds used by patients who had suffered from dysentery, and who had been removed to the hospital; and as each person in the wards was furnished with a separate vessel, a solution of bichloride of mercury was ordered to be placed in the vessels of all who were affected with diarrhea in any form. The good effect of these

measures was immediately apparent, for while there were thirteen deaths from dysentery in June, and seventeen in July, there were only four in August, and none at all in September, until the 25th of the month. In fact, only one death occurred among those who were attacked with dysentery after the closet was cleaned, and in this case the immediate cause of death was cerebral hemorrhage. From August 10th to September 25th, no new cases appeared. During the interval between July 18th and September 15th, the closet was cleaned a number of times. For about ten days preceding September 25th, the closet was not cleaned, and at this time a number of new cases and several deaths occurred. Certainly, more conclusive proof could scarcely be desired of the causative relation existing between the condition of this closet and the appearance of the epidemic.

But there were still other facts that pointed strongly in this direction. Among the inmates of certain wards who made use of a closet in the main building, which was provided with school-sinks and was in excellent condition, very few cases of dysentery occurred at any time during the summer; and it was ascertained that among these few in every instance those affected had used the general closet referred to, at least a portion of the time, while not a single case appeared among those who used exclusively the closet in the main building. Again, no cases of dysentery occurred during a period of nearly seven weeks, from August 10th to September 25th (when the closet was kept clean), at a time when a larger number of cases would naturally be expected than in June or July. Thus, in September, 1884, more cases occurred than in any one of the summer months.

In some of the several cases of dysentery, as shown by the post-mortem lesions, there were, so far as could be learned, neither tenesmus nor blood nor mucus in the stools at any time during the course of the disease. A comparatively large number of autopsies were made, and there were always present practically the same lesions, namely, those of a very severe follicular and diphtheritic dysentery. The lower part of the descending colon, the sigmoid flexure, and the rectum, were in the majority of cases the parts most seriously affected; but the ulceration always involved, to a certain extent, the other parts of the mucous membrane of the large intestines, and in a number of instances had extended for almost eighteen inches up into the ilium. In some of the more severe forms of the disease the largest part of the mucous membrane was entirely destroyed by the enlargement and coalescence of the follicular ulcers combined with the ulceration following a diphtheritic inflammation. The process in the portion of the small intestine referred to, was for the most part of a diphtheritic character. In the cases where the disease pursued a more chronic course, the walls of the large intestines were greatly thickened and infiltrated with inflammatory products, while the mesenteric glands were enlarged.

Having described the clinical history of the severe cases, Dr. Biggs said that the treatment which was most successful in all except the later stages of the disease, when it became chronic, consisted in a combination of castor oil and opium with a strictly milk diet. In the later stages, bismuth or nitrate of silver and opium were given. In addition to these remedies enemata of starch and opium were used in some cases. Cocaine was also added to these enemata in a few in-

stances. Enemata would have been used on a large scale had it not been for the fact that they could not be given satisfactorily by the nurses in charge.

This epidemic of dysentery he thought was interesting from the almost conclusive evidence presented of the causal relation existing between the exposure to the emanations of decomposing human excreta and the appearance of the disease. There could be no doubt, in his opinion, that epidemic dysentery was an infectious disease, due to the action of some definite micro-organism. There was much evidence to show that dysentery, under certain conditions, is contagious; but, apparently, like typhoid fever, it was generally a miasmatic contagious disease propagated by the stools of dysenteric patients. The difficulty of isolating from the stools the specific micro-organism which causes any disease of the alimentary canal was very great, and Dr. Biggs, in conclusion, expressed his regret that he was not able to make any satisfactory investigations on this point.

The President, DR. CHARLES A. LEALE, said that he had often met with obstinate cases of follicular enteritis and dysentery in some of the most expensive houses in New York, and that in most instances it was ascertained that the cause of the trouble lay in some defect in the drainage. He had known of a number of houses about which there seemed to be a fatality; since several persons who had previously been in good health successively died of this kind of disease, after becoming residents of them.

The Secretary, DR. P. BRYNBERG PORTER, said that a few years since he had occasion, in connection with the State Board of Health, to investigate an epidemic of dysentery occurring in a village on Long Island, in which it was found, by expert analysis, that in every instance the well-water of the premises where the case occurred was contaminated; and it was ascertained, furthermore, that the position of the privy in reference to the well was such that defilement of the drinking water by human excreta was possible. His report of the outbreak was published in the Second Annual Report of the New York State Board of Health (1882).

DR. J. W. S. GOULEY read a paper entitled,

#### A PROTEST AGAINST INDISCRIMINATE MEATUS CUTTING.

Of late years, he said, the import of such consequences of urethral strictures of the balanic region such as dysury, vesical irritation, and reflex neuroses, had been greatly overestimated, and this had often led to very rash and unwarranted surgical interference. Meatus cutting, or to give the operation a proper technical name, porotomy, has become the fashion, and every adolescent and adult who is not afflicted with congenital hypospadias must have his meatus cut; for he is told that the nozzle of his urine-hose must be of greater calibre than the hose itself. The doctrine that the meatus should be the largest part of the urethra, Dr. Gouley contended, was not only unsound, but most dangerous, and it was leading to much evil. It was, therefore, high time to protest against the indiscriminate performance of porotomy, and particularly against those incisions which resulted in deformity of the urethra. The congenitally narrow meatus is very often met with, and yet comparatively few patients were ever inconvenienced by this defect. In many cases the meatus barely admitted a catheter of

the diameter of three or four millimetres; and when this condition of affairs was present it was, of course, necessary to enlarge it by incision to a degree sufficient to permit the easy passage of evacuating catheters, or of a fair-sized lithotrite, should the presence of a vesical stone render necessary the use of such an instrument. But to incise through and through the whole balanic region was, he thought, as unwarranted as it was unsurgical. Many men with an abnormally small meatus would never become aware of that fact but for the occurrence of an attack of urethritis.

Strictures of the balanic region were not ordinarily amenable to treatment by dilatation, but required incision; which was the most prompt and efficient method that could be employed for their eradication.

The incision, however, should be directed and proportioned in accordance with the size of the glans and the condition of the extremity of the urethra. When, for instance, the meatus was normally situated, a sufficiently free central cut along the floor of the urethra answered the purpose of simply enlarging the contracted urethral extremity within proper limits; but when there happened to be a slight balanic congenital hypospadias, this kind of incision only increased the deformity, and failed to relieve the stricture; which could be successfully treated only by bilateral perotomy, performed in such a way as not to increase the hypospadias.

The probable object of these extremely free incisions of the urinary meatus was, that instruments of extremely large calibre might be introduced through strictures of the deeper parts of the urethra. This was another of the many prevalent surgical heresies. The ostensible reason for this over-stretching of the urethra was that the stricture or strictures might not recur; but the careful observation of many cases treated by the introduction of sounds of the diameter of eleven, twelve and thirteen millimetres, into the average human urethra, showed that while the stricture in some instances did not recur, the urethra, as an organic channel, was entirely spoiled. It became, as compared with a normal urethra, what an old, worn-out, hardened rubber-tube was to one which had just come out of the maker's hands. The urethra, when constantly distended, soon lost a very considerable number of its mucous follicles, and became dry, leathery, inelastic, patulous, and no longer capable of successfully propelling the urine, which slobbered out of a wide mouth instead of being forced in a well-formed stream through a narrow outlet. The genital functions were also said to be impaired by this over-distension of the urethral canal. Dr. Gouley considers that it is never justifiable to over-distend the whole urethra. Useful instruments, he said, had been devised to obviate this evil, which were so constructed as to over-distend the strictured part of the urethra only, and save injury to the normal part of the canal, but they were but little used. Dilating instruments of this kind he thought should be occasionally employed during the treatment of strictures in the deep urethra; but the main object of moderate dilating catheterism was to restore the urethra as nearly as possible to its normal suppleness.

At the conclusion of the paper Dr. Gouley presented the photograph of the penis of a patient who had been in Bellevue Hospital for some months, which he said furnished an excellent illustration of these enormous perotomies. In this instance the whole of

the balanic portion of the urethra had been cut through and through; thus constituting a marked case of traumatic hypospadias made with the design of relieving a stricture in the part, which, it was needless to say, had not been accomplished. This was only one out of at least fifty such cases that he had observed; but it would be readily understood that he himself pleaded guiltless of the operation.

The paper was discussed by Drs. John Shady, Isaac E. Taylor and Alfred L. Carroll. The latter remarked that it had always seemed to him that Divine Providence did not quite intend that the mouth of the urethra should be made to resemble the shape of an old-fashioned blunderbuss. The idea that it should be was opposed to common-sense; and he was glad to have the opinion which he had formed confirmed by so high an authority as Dr. Gouley.

Dr. FRANK GRAUER presented a specimen of

#### EXTRA UTERINE PREGNANCY.

in which the seat of the development of the ovum was in the Fallopian tube, close to its exterior orifice. The patient, a lady of twenty-six years, in her third pregnancy, had died very suddenly from rupture of the cyst, and the diagnosis was made before death. At the autopsy the fetus, which was apparently of the age of seven or eight weeks, was found among some clots in the abdominal cavity. There were three points of special interest about the specimen, namely:

- (1) The presence of a decidua vera in the uterus.
- (2) The sympathetic enlargement of the walls of the uterus.
- (3) The thickening of the posterior part of the Fallopian tube at the point of the rupture.

Dr. BIGGS, presented for Dr. E. G. JANEWAY, who was unable to be present, a specimen of

#### PRIMARY CARCINOMA OF THE CYSTIC DUCT,

with abundant secondary carcinomatous deposits in the liver and the stomach. The special points of interest were, the primary growths in the cystic duct, which is a rare location for such trouble, and the marked difference between the primary and secondary growths; the former being so insignificant as almost to escape notice, while the latter was of the most extensive character.

#### THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting, January 20, 1887.

Dr. J. H. RIPLEY read a paper on

#### THE VALUE OF QUININE AS AN ANTIPIRETIC IN PNEUMONIA.

The experiments on which his observations were based were commenced, in 1877, at St. Francis's Hospital, New York, and had been continued since by successive house-physicians, acting under his direction. Although many more had been made, the experiments available for the purpose designed were forty-eight in number, conducted in patients varying from nineteen to forty-five years of age.

The plan carried out was to give quinine as early as possible in the course of the disease; but only in complicated cases, and in those in which the temperature was, at least, 103°. Each patient was watched for several hours before the experiment was commenced, and all the observations of temperature were taken with

the thermometer in the rectum. The experiment lasted less than four hours, and the majority were continued for from twelve to fifteen hours. The time of day at which the quinine was administered varied; but when a single dose was used in the twenty-four hours, it was given in the morning. In twenty of the experiments a single dose of twenty grains was given; and in eight, a single dose of forty grains. It was usually given in solution; but, in some instances, was used hypodermically. In two of the patients there was no reduction of temperature whatever noted after the use of quinine; and in two a slight elevation occurred. The reduction of temperature effected by the quinine never lasted for more than from two to four hours.

The effect of the remedy on the pulse and respiration was not a constant guide to its effect on the temperature. It varied in different cases, but the pulse and temperature were usually reduced in frequency. In about half the cases, the temperature was lowered between one and two degrees under the use of quinine. In the other half, the reduction was less than half a degree. In many cases the antipyretic effect of the drug was only apparent; and the reduction of temperature was, in reality, due to natural causes.

The conclusion arrived at by the author was that quinine was a feeble and uncertain antipyretic in pneumonia. But this was not all. It had a bad effect on the appetite and digestion, and not infrequently excited nausea and vomiting. In addition, it was liable to produce marked cardiac weakness, profuse cold perspiration, and profound nervous depression. Opisthotonos was noticed in one instance, and in many cases it caused epistaxis. In three cases the urine was examined before and after the ingestion of large doses of quinine; and in one, the urine, previously normal, was found to contain large quantities of albumen, hyaline casts, and renal mucus, after the use of the drug. These bad effects, he thought, more than counterbalanced any good effects that could be attributed to it.

Moreover, Dr. Ripley could not see that it had, in any case, shortened the natural course of the disease. In some instances the pneumonic consolidation had extended under its use. In general, he believed that too much importance was, at the present day, attached to the reduction of temperature in febrile diseases. In typhoid and other fevers, much better results had been obtained at St. Francis's Hospital since heroic measures for reducing temperature had been given up. That quinine had any effect in preventing cell-migration, as claimed by certain authors, he thought was extremely doubtful. In conclusion, he expressed the opinion that large doses of quinine in pneumonia should be abandoned. If an antipyretic effect were required, we possessed much more efficient agents of this class in antipyrine and salicylate of sodium.

DR. MARY PUTNAM JACOBI read an abstract of a paper on the use of quinine in the pneumonia of children, which she had presented at a recent meeting of the Section on Practice. Of one hundred cases of broncho-pneumonia in children, of which she had notes, fifty-nine were available for statistical purposes. They were treated in the out-patient department of Mt. Sinai Hospital, and their average age was two and one-half years. Seven deaths were known to have occurred. She spoke of the effect of quinine on the physical signs and on the fever, and said that no decisive results could be gathered from the cases. Five grains,

night and morning, seemed as efficient as larger doses in children. The conclusion that she arrived at was that quinine was not to be relied upon as an antipyretic in the pneumonias of children; and that it was an efficient remedy only so far as it affected the morbid process present. It did tend, she thought, to limit the secondary extension of the disease.

DR. R. C. M. PAGE, Secretary of the Section on Practice, reported some remarks by Dr. J. Lewis Smith at the meeting of the Section referred to. Dr. Smith said that, as Dr. Mary Putnam Jacobi's cases occurred in dispensary patients, it could not be known whether the quinine was vomited or not. This drug was exceedingly liable to excite nausea in children; and the best way that he had found to administer it was in connection with wild cherry bark. He was in the habit of giving one large dose, with a view to preventing cell-migration, after which he preferred to give it in doses of from one to one-and-one-half grains every four hours. It was a useful tonic, and he thought it prevented secondary lesions.

DR. FRUITNIGHT said that it had been the common practice to give quinine for almost everything; but since the introduction of other antipyretics, he thought the tendency had been to discard it to a large extent. The reaction was like the swinging back of the pendulum, and it seemed to him that it was the part of wisdom to pursue a middle course. This experience with quinine as an antipyretic in pneumonia coincided with that of Dr. Ripley; but, at the same time, he intended to continue to use the drug in this disease, not for its antipyretic, but for its sustaining, effect. To secure this, it should be given in small doses. One great danger in pneumonia was cardiac failure; and, in large doses, quinine was supposed to have a tendency to produce this.

DR. F. A. CASTLE said that his experience fully bore out that of Dr. Ripley, as to the uselessness of quinine in pneumonia. Ten years ago Bing had recommended it in large doses; giving as much as seventy grains in twenty-four hours. Personally he had never carried it to this extent, but he had used it in as large quantities as the stomach would bear. He had found, however, that if the temperature was to be reduced by quinine, it must be at the expense of the nutrition of the patient. In the broncho-pneumonia of children, if carried beyond tonic doses, it had a bad effect upon the stomach, and also tended to produce delirium. For the last five years he had almost entirely abandoned this remedy in pneumonia. As regards sustaining the heart, he thought one had a much more reliable agent than quinine, in digitalis.

DR. BILLINGTON said that, like Dr. J. Lewis Smith, he had found quinine very apt to produce vomiting in children, and he had therefore found great satisfaction in giving it in the form of a suppository. In case any rectal or anal irritation were caused by this method, it could easily be entirely avoided by the use of a simple apparatus provided with a piston-rod, which could now be obtained for the purpose. By employing this, the administration could be kept for any length of time desired without the slightest inconvenience. He therefore considered the method of giving quinine by the rectum one of great practical value. In pneumonia he had been disappointed in quinine as an antipyretic, and he had also found that its use was attended with other bad results. In children the natural tendency was to recover, both in broncho-

pneumonia and in ordinary pneumonia, and a large number of cases would get well without any treatment at all.

DR. L. EMMETT HOLT said that of twenty cases of pneumonia in children, treated by him with quinine or cinchonidia, in twelve the drug was given in sufficient doses, and for a sufficient length of time, to enable him to form some opinion of its action; and in nine it was a total failure, so far as any effect upon the temperature was produced. He gave as much as sixteen to thirty grains a day to children from one to one-and-a-half years old; and in two or three cases the temperature rose steadily after the quinine had been taken. His own feeling was, that as an antipyretic, quinine in small doses was useless, and in larger doses dangerous. When the fever was high much better results could be obtained from the judicious and continued use of the cold pack. By this means he had been able to save a number of children whose cases were apparently hopeless. Unless the temperature reached a very high point, however, he was doubtful about the efficacy of antipyretic treatment in pneumonia. For the past two years he had abandoned quinine entirely in acute pneumonia, as he had found that it almost always gave rise to vomiting and other bad results; and since he had discontinued its use he had met with at least as good, if not better, success in his treatment. Quinine, however, was of very marked advantage in convalescence and in protracted cases of bronchopneumonia, if given in small doses.

The President, DR. A. JACOBI, said that he had seen a number of changes in professional opinion concerning quinine, since he commenced practising in New York, thirty years ago. At that time it was given in doses of half-a-grain or a grain to adults, and in smaller doses to children; and much was expected from it. It was true that a large number of cases got well; but they were the kind of cases alluded to by other speakers in which the natural tendency was to recovery. It was only in the bad cases, however, that we could judge of the real effect of a remedy. At that time, and ever since, he had been in the habit of giving six, eight, ten and twelve grains of quinine to children, and it was his practice to administer it deliberately at certain times of the day. He usually gave full doses in two installments in the morning, when the remission occurred: say five grains at eight, and five at eleven. If it did not affect the stomach unfavorably, however, he would give a single full dose in the morning.

He thought that a good deal of the inefficiency of the remedy which had been spoken of, was due to the condition of the stomach incident to the febrile state, which prevented it from absorbing; and thus the quinine was not digested. The same was true of the condition of the rectum. Therefore, he preferred to give it hypodermically; and when this method was used the good effect of the drug was apparent in a short time. A reduction of temperature could thus be effected, which was impossible with quinine used in any other way. The best preparation for hypodermic injection was the carbamide, on account of its great solubility. There was no use in giving quinine if the temperature did not rise above 102; and it was to be borne in mind that it should by no means be given in every case of pneumonia, but only in occasional instances. In many cases, when the fever was high, antipyrine was excellent.

DR. RIPLEY said that in quite a large number of the cases referred to in the paper, the quinine was given by hypodermic injection; yet the result was the same as in the other cases. The muriate in strong solution was the preparation employed. In many of the protracted cases to which reference had been made in the discussion, he believed that there was an associated pleurisy, and this is often a difficult thing to recognize in children. As to the use of antipyretics in general, he said that in an asylum with which he was connected, sixty cases of measles had recently occurred. A considerable number of them were treated with antipyrin, but it soon became apparent that these children did not do as well as those treated by the ordinary simple methods.

DR. JACOBI remarked that it was not safe to use too concentrated a solution of quinine for hypodermic injection, and related a case he had met, in which, at the autopsy it was found that the quinine was all deposited in the cellular tissue, the water of the solution only having been absorbed.

### Recent Literature.

*Clinical Manual for the Study of Medical Cases.* Edited by JAMES FINLAYSON, M.D. Second Edition, Revised and Enlarged. With 158 Illustrations. Philadelphia: Lea Brothers & Co. 1886.

Although this book has been revised, re-written in parts and considerably enlarged, it still retains the characteristics of a genuine *manual*, and that is absolutely essential in a work whose aim is to "afford such assistance as students, actually working at clinical medicine, might seem to require."

The volume is practically the product of the Glasgow School of Medicine. There are five contributors beside the editor; all six contributors, with one exception, are connected with the Glasgow medical institutions. Among the contributors we find the well-known names of Drs. W. T. Gairdner and Joseph Coats. To students of clinical medicine this book can be recommended as a convenient and suggestive one.

*Handbook of Practical Medicine.* By DR. HERMANN EICHHORST. Volume IV. Diseases of the Blood and Nutrition, and Infectious Diseases. Seventy-four Wood Engravings. New York: Wm. Wood & Co. 1886.

This is the December number of "Wood's Library of Standard Medical Authors." The title-page gives a quite distinct idea of the scope and contents of the volume; a statement which is not necessarily a truism. The division on diseases of the blood includes diseases of the blood-producing organs, meaning thereby diseases of the spleen. Diseases of nutrition are represented by obesity, gout, diabetes mellitus and insipidus, rickets, osteomalacia, and arthritis deformans.

Infectious diseases are divided into (a) those with typical localization, and (b) those with variable localization, under which latter head are placed tuberculosis, syphilis, leprosy, diphtheria, and the zoonoses, namely, diseases communicated from animals to men.

The question of treatment is not neglected under the different headings. The illustrations are numerous, well selected and fairly executed.

*Wear and Tear, or Hints for the Overworked.* By S. WEIR MITCHELL, M.D., LL.D. Fifth Edition, thoroughly Revised. Philadelphia: J. B. Lippincott Co. 1887.

We welcome another edition of this little brochure, which originally appeared as a magazine article fifteen years ago. Its object is to warn the writer's fellow-countrymen against what is still their besetting sin—especially in the northern half of the United States—namely: overwork, excessive haste and excessive waste.

To this physiological iniquity our political and social institutions, as well as our climate, impel, and it will be a long time before the proportion of the population in sore need of the gospel which Dr. Mitchell preaches will be sensibly diminished, notwithstanding certain indications of a tendency in the right direction.

This is the kind of tract we should like to see widely distributed by some society for the propagation of health and happiness at home. We suppose, however, that the legacies will still go to the enlightenment of the distant heathen in regard to everlasting punishment.

*Diseases of Tropical Climates.* Lectures delivered at the Army Medical School. By WILLIAM CAMPBELL MACLEAN, M.D., C.B., Professor of Military and Clinical Medicine, in the Army Medical School, Netley. London and New York: MacMillan & Co. 1886.

As the title implies, this volume of 337 12mo. pages, is made up of lectures delivered before the students of the Army Medical School at Netley, near Southampton, England. It will most naturally find its readers among the class of men to whom the lectures were originally addressed. The diseases treated of are the fevers, diarrhoea and dysentery, cholera, beriberi, guinea-worm, diseases of the liver, malaria, insolation. In a word, diseases which, though not peculiar to, are all very prevalent in British India.

The lectures are necessarily somewhat elementary, and attention is directed to such points as may be practically useful to the future surgeon in the British army. The very latest and most fashionable medical novelties are conspicuously absent, and an attitude of marked reserve, amounting even to neglect, is exhibited towards specific disease-germs. In connection with beriberi no mention is made of a microbe; in regard to the spirillum of relapsing fever the impression is given that it has not been successfully inoculated upon monkeys, the reverse being the case, and that it is probably simply an epiphenomenon; Kleb's bacillus is mentioned in the lecture on typhoid fever, but the later and better accredited bacillus of Eberth and his followers is not referred to; Marchiafava's investigations are barely alluded to, and his colleague (Celli) in the study of the *plasmodium malarie* is apparently concealed under the name of Valenti.

Dr. Maclean has always held, he states, that typhoid fever can arise *de novo*, but the examples which he gives in support of such a conviction are not very convincing. The absence of an index would be a drawback to the general usefulness of the book.

*On Fevers, their History, Etiology, Diagnosis, Prognosis, and Treatment.* By ALEXANDER COLLIE, M.D. With Colored Plates. Philadelphia: P. Blakiston, Son & Co. 1887.

Dr. Collie was for many years resident physician in charge of the Homerton Fever Hospital of London,

and is now medical superintendent of the fever hospitals in the eastern part of that city. His field of observation has been a wide one, and his extensive experience has peculiarly suited him for writing instructively about the subject which he has chosen. Dr. Collie regards typhoid fever as a specific disease due to a specific cause. He rejects the idea of a *de novo* origin, but elsewhere exhibits a somewhat inconsistent sympathy for Bastian's views in favor of spontaneous generation in the abstract. The germ theory, in his opinion, may be a good working hypothesis, but cannot yet be regarded as a complete explanation of the acute infectious diseases, and he makes no reference to the latest results of Eberth and Koch in regard to the typhoid bacillus. The typhoid stool he thinks, and probably justly, is infectious from the time of its passage. The Pettenkofer-Buhl theory that the prevalence of this disease is directly dependent upon the level of the ground-water, being in an inverse ratio to that level, does not find favor with him; and again we believe his judgment is sound. Cold water externally, his experience leads him to regard as an occasionally useful adjuvant in treatment, but not as a good method of treatment. His remarks upon the uselessness of astringents internally and of the ice-bag externally, in intestinal hemorrhage, are sensible and to the point.

The incubation of scarlet fever he states may vary from some hours to some days; but a case cited (p. 331) to prove that its incubation was only eleven hours seems to us, as reported, by no means conclusive.

The volume, a small octavo, contains 288 pages; the chromo-lithographs, of which there are four, are good.

*Surgical Diseases of the Kidney.* By HENRY MORRIS, M.A., M.D., F.R.C.S., Surgeon to, and Lecturer on Surgery at the Middlesex Hospital, London. 12mo. 555 pages, with 6 chromo-lithographic plates and 40 engravings. London: Cassell & Co. Philadelphia: Lea Brothers & Co. 1886.

Mr. Henry Morris is a surgeon who has had a large and valuable experience in the surgical diseases of the kidney, and who has won for himself an enviable reputation in the field of renal surgery.

We have been afforded much pleasure in reading this "Manual," which is ideal in the completeness with which the subject is treated. The work contains more than a brief description of the normal regional anatomy of the kidney; a full account of the malformations and other abnormal anatomical conditions of the organ; a systematic account of the injuries and diseases of the kidney; and finally, a fairly full account of the methods of performing the several renal operations. It is arranged systematically, with an excellent index, and has a full reference to the literature of each subject under its appropriate chapter.

The engravings and chromo-lithographs reflect great credit upon the publishers, and must be a source of satisfaction to Mr. Morris.

The work is a full, careful exposition of one of the most important parts of the field of surgery, and its perusal enables a surgeon to be abreast with the times.

*How We Treat Wounds To-Day. A Treatise on the Subject of Antiseptic Surgery which can be understood by Beginners.* By ROBERT T. MORRIS, M.D. Second Edition. New York and London: G. P. Putnam's Sons. 1886.

As giving the views of the extreme "antisepticians" in an amusing style, we would commend to the notice of the profession this book, which opens with the statement that "this book is modest only in size." The book, if it were addressed to surgeons away from the centres of professional activity, might be said to give in a strikingly clear manner the details of the antiseptic treatment of wounds; but, as it is "a treatise on the subject of antiseptic surgery which can be understood by beginners," we feel that it is somewhat unsafe, from the visionary manner in which it presents the subject.

We sympathize with Dr. Morris in his feelings regarding consultations with surgeons whose brain-cells have become ankylosed, but such sentences as the following (page 132): "Don't call a consultation; because some one may want to wait a little while," or "Don't ask any one's advice, but tell your assistants what is to be done," should be omitted from a work addressed to beginners. We trust that the next edition of this book will have a modicum of caution which will leave the mass of enthusiasm which pervades the whole.

*A Text-Book of Medicine for Students and Practitioners.* BY DR. ADOLF STRÜMPFELL. Translated by permission from the Second and Third German Editions, by Herman F. Vickery, A.B., M.D., and Philip Coombs Knapp, A.M., M.D., with Editorial Notes by Frederick C. Shattuck, A.M., M.D., with one hundred and eleven illustrations. New York. D. Appleton & Co., 1887.

The first edition of this book by Dr. Strümpf appeared in 1833, when the author was professor at the Medical Polyclinic of the University of Leipzig. It immediately achieved a deserved popularity as a text-book in Germany, where it has passed through three editions. We do not doubt that a very cordial reception and intelligent appreciation, proportioned to its merits, await it in this country.

It is a work of one octavo volume of 981 pages, of good clear type, and not unwieldy; the translation is remarkably well done; and moreover, the translators have allowed themselves some slight liberties calculated to increase its worth for American readers. The editor has, with the same end in view, added occasional notes which are incorporated in the text and bracketed. This was a wise step, and has been judiciously executed.

Dr. Strümpf's book is full, but concise and very practical; hypotheses have been omitted; it does not remind one in any way of the *Schreibtsch*, but it carries an easy conviction that the author has been a persistent and accurate observer of the sick. His clinical conclusions are built upon a firm foundation of anatomy and pathology. The chapters on diseases of the nervous system are especially complete and satisfactory.

The book, in a word, as a text-book, exhibits the merits of the best American books of a similar character, as well as those German recommendations which we should expect to find in a high degree; and the author has, at the same time, known how to avoid those defects to which his countrymen are prone when they sit down to write. We believe both practitioners and students of medicine will find this translation of Dr. Strümpf's work a very useful and valuable acquisition.

*The Emancipation of Massachusetts.* By BROOKS ADAMS. Boston and New York: Houghton, Mifflin & Co. 1887.

Aside from its interest for the general reader which this book possesses as a vivid description of early New England life, it claims special attention from students of anthropology, as an important application of the laws of nerve action to mental phenomena.

The writer, without making any claim to be considered an expert in natural science, points out facts and suggests relations which cannot fail to awaken the interest of the ethnologist, the physiologist, and the psychologist.

Starting from the observation that "there would seem to be a point in the pathway of civilization where every race passes more or less completely under the dominion of a sacred caste," Mr. Adams seeks to discover the means by which this dominion has been secured, as well as the circumstances which have led to its subsequent overthrow. The origin of the priestly power he traces to the discovery of some valuable secret (for example, a cure for the bite of the rattlesnake), which gives to the finder, and those to whom he imparts it, a character of peculiar sanctity. Societies formed of individuals possessing knowledge of this sort, and claiming for it the authority of divine revelation, soon develop into hereditary priesthoods, administering elaborate rituals, which exert over the mind the same coercive power that firmly-established physical habits maintain over the bodily movements.

As military commanders seek, by the constantly-repeated evolutions on the drill-ground, to convert their armies into "machines wherein subjection to command is instinctive, and insubordination, therefore, practically impossible," so a priesthood endeavors to establish its authority over the minds of men by exacting, from the earliest childhood, an unquestioning compliance with complicated forms and ceremonies, whereby mental processes are rendered as automatic as the motions of a well-trained soldier.

Emancipation from this ecclesiastical control can be effected only when the intellectual faculties are sufficiently developed to hold in check this mental automatism; and, on this theory, original thought must be regarded, from a physiological standpoint, as the inhibition of a mental reflex. The individuals who first manifest this tendency to intellectual variation are, of course, recognized by the priests as their deadliest foes, and are persecuted with relentless severity.

The reason why the early history of New England exhibits, in a condensed form, many of the phenomena which usually belong to a more primitive stage of development, is that the early colonists, having taken the Bible for their literal guide in all the affairs of life, actually undertook to reproduce, as far as was possible in the 17th century, the social condition existing among the Jews of the 7th century B. C.; and really did succeed in establishing "a theocratic despotism, which lasted, in full force, for more than forty years."

In this connection, no attempt can be made either to weigh the historical evidence which the writer brings to the support of his thesis, or to point out certain objections which may be urged. It is safe to say, however, that Mr. Adams has pointed out an important analogy between mental and physical evolution, and has illustrated it in a very vivid and effective way by examples drawn from the early history of this community.

THE BOSTON  
**Medical and Surgical Journal.**

THURSDAY, MARCH 3, 1887.

*A Journal of Medicine, Surgery, and Allied Sciences, published at Boston, weekly, by the undersigned.*

SUBSCRIPTION TERMS: \$5.00 per year, in advance, postage paid, for the United States and Canada; \$6.00 per year for all foreign countries belonging to the Postal Union.

All communications for the Editor, and all books for review, should be addressed to the Editor of the Boston Medical and Surgical Journal, 283 Washington Street.

All letters containing business communications, or referring to the publication, subscription or advertising department of this journal, should be addressed to the "Manager of the Business Department," Medical and Surgical Journal, 283 Washington Street.

Remittances should be made by money-order, draft, or registered letter, payable to

THE PATELLAR REFLEX.

IN 1875 Erb and Westphal<sup>1</sup> published simultaneously the results of their independent studies on the shock of the tendons, and the patella-tendon in particular. Light taps with the finger or side of the hand made over the tendinous insertions of certain muscles (quadriceps femoris, the crural muscles, the triceps in the upper arm), cause a peculiar starting of those muscles, likened to a kick or a jerk. Westphal gave the name of "lower leg phenomenon," "foot phenomenon," to what Erb had designated as "patellar reflex," "reflex-ankle clonus," and while the latter regarded these as reflex acts, due to excitation of the tendons, the former considered the muscular contractions as produced directly by mechanical stretching and shock of the muscular substance. Westphal's view has been supported recently in this country by Drs. S. Weir Mitchell and M. J. Lewis,<sup>2</sup> and by Dr. Warren P. Lombard, in the *American Journal of Medical Sciences*, for January, 1887, in an article: "Is the 'knee-kick' a reflex act?" Their studies led Drs. Mitchell and Lewis to believe that the knee-jerk and other like responses to tendon taps are direct muscular acts, which cannot exist without that spinal contribution known as "tone," a contribution capable of increase from a variety of causes, and they hold that these muscle responses to a pull on the tendon, cannot be reflexes, because the latter are inhibited by violent sensory stimulations which they find increase the knee-jerk. The great argument against the theory that the "knee-kick" is a reflex act, and which is well stated by Dr. Lombard, and is fortified by his experiments, is "that the time elapsing between the moment of the blow on the ligament, and the beginning of the contraction of the quadriceps muscle is too short for a reflex action." "Thus the majority of observers find the interval to vary between 0.030 of a second and 0.040 of a second, except under abnormal conditions, when—in lateral sclerosis for example—

it has been found as short as 0.016 of a second. Such intervals of time are compared with the presumable reflex time, and are found to be three times as short as they should be, were the action a reflex process."

The advocates of this view do not deny the participation of the spinal cord in the tendon-phenomenon, but regard this influence as concerned in regulating the "tonicity" of the muscles, whose contraction causes the characteristic jerk. When the functions of the cord are exalted—as in the erethism of lateral sclerosis—the phenomenon is more pronounced, for the "muscle tonus" is exaggerated; when the vital properties of the cord are depressed, or the nerve conductors by which the "tonus" is imparted are incapacitated by traumatism or by disease, (some cases of locomotor ataxia, sections of the cord in the lumbar region, sections of certain nerves), the tendon-phenomenon is wanting. Practically it makes but little difference which theory be entertained. If the "knee-jerk" be found to have all the characteristics of a reflex act, the ordinary medical mind will be inclined to think that there is some mistake about the "time argument," especially when it is admitted that the time required for reflex acts of all kinds is not absolutely determined.

It is worthy of note in this connection that Burekhardt and Tschiriew, as well as Ter Meulen, Gowers and Brissaud have arrived at views differing from those of Lombard, concluding from their experiments "that the time which separates the shock of the tendon from the contraction of the triceps is sufficient in order that this contraction may be effected by reflex mechanism."

The arguments chiefly relied on to prove the reflex nature of the knee phenomenon are as follows:

(1) Experimenters, as Lewinsky, have noted that under the influence of excitation of the tendons, when the reflex properties of the spinal cord are exalted, there is contraction, not only of the muscles whose tendons are excited, but also of the antagonist muscles.<sup>3</sup> Here the intervention of the spinal cord is evident.

(2) The shock of one patellar tendon sometimes causes contraction, not only of the quadriceps muscle on the side of the percussion, but also of the adductor muscles of the opposite side. Erb has witnessed this in hemiplegic patients.<sup>4</sup> Tschiriew and J. L. Prévost have observed the same phenomenon in their experiments on hares.<sup>5</sup>

(3) Experiments on animals seem to teach the reflex nature of the muscular contraction in question. The first experiments were those of Schultze and Furbringer,<sup>6</sup> who found that after section of the crural nerve in hares, the knee-jerk failed to appear. This shows that "the contraction of the triceps is not the result of a direct arousing into activity of the fasciculi of this muscle by mechanical shock, and that reflex

<sup>2</sup> Physiological Studies of the Knee-jerk, etc. Medical News, February 12, 20, 1886.

innervation plays an indispensable rôle in the production of the phenomenon." Schultze and Furbringer have also shown that the percussion of the patellar tendon on one side in the hare may provoke a contraction of both triceps muscles, the contraction on the side receiving the shock being considerably stronger than that of the opposite side. This phenomenon has also been witnessed by Burekhardt and Prévost. It is hard to explain this fact on any other theory than that of reflex action.

An interesting fact in this connection is communicated by Tschiriew.\* If section of the crural nerve abolishes the possibility of the patellar reflex, section of the sciatic nerve at the upper part of the thigh exaggerates this reflex. "It would be impossible," says Vulpian, "to explain this influence of the section of the sciatic, if the spinal cord did not play an important rôle in the production of this phenomenon, for the sciatic has absolutely nothing to do with the innervation of the triceps femoris muscle." Why section of the sciatic should cause exaggeration of the patellar reflex is not known, unless the paralysis of the muscles which antagonize the triceps, and which are supplied by the sciatic, and the consequent exaltation of the functions of the triceps, be a sufficient explanation.

These considerations, among others which might be added, go to show that the term "tendon-reflex," cannot yet be regarded as discredited.

#### ENLARGEMENT OF THE THYROID GLAND IN PREGNANCY AND PARTURITION.

IN the present state of uncertainty regarding the function of the thyroid gland we can hardly expect to attain much definite knowledge as to the connection which, from a period at least as remote as that of the poet Lucullus, this gland has been supposed to possess with the generative function in woman. That there is some such connection seems to be shown by the testimony of obstetric writers, such as Simpson, Barnes, and Lusk, that enlargement of the thyroid gland occurs not unfrequently during pregnancy. This, of course, may be simply a phase of the generally increased glandular activity which characterizes the puerperal state, or it may be the direct effect of the enhanced action of the heart, whereby blood is forced into the abundant vascular channels of the gland which lies so near it. The tumor, however, in at least one recorded autopsy, represented a true follicular hypertrophy, a multiplication of the normal elements and not a vascular enlargement.

Dr. Natalis Guillot seems to have been the first to draw attention to bronchocele as an accompaniment of pregnancy, an occurrence which he noticed at first incidentally in the wards of the Necker Hospital, the patients not complaining in any way of the enlargement. Ollivier, in his "*Etudes sur les Maladies Chroniques d'origine Puerperale*," described various

forms of the affection: first, a subacute and transitory form, appearing at the third or fourth month of pregnancy. Here there is no pulsation as in vascular goitre and no exophthalmos. Second, a rapidly growing variety, especially dangerous through suffocation; third, an enlargement, slow in pregnancy, stationary after delivery, liable to undergo a slight increase in size with each succeeding gestation. This variety is the commonest.

There is a wide divergence between various authors in the frequency which they assign to tumefactions of the thyroid in pregnancy. Freund, who measured the necks of a number of pregnant women, came to the conclusion that forty-five out of fifty had an increase in the volume of the neck as the result of pregnancy. Burine believes that goitre is very frequent in pregnant woman, though often overlooked through lack of careful measurements. Tait, in a communication to the Obstetrical Society of Edinburgh, in 1873, reported some twenty cases which had come under his own observation. Of these all but one occurred in one locality, at and near the town of Wakefield. After removing to Birmingham, in a very large hospital clientèle, he saw only one such case. Hence, he concludes there is some endemicity to the affection. The speakers who discussed Mr. Tait's paper had none of them apparently seen as many cases as Mr. Tait, though one, Mr. C. Bell, had seen three cases in one family in Lanarkshire. These were in a cottage situated low and surrounded by trees. Dr. Matthews Duncan and Dr. Keiller had seen the affection in pregnancy, but did not consider that its uterine relation was solely with pregnancy, but as well with the general condition of the glandular structures of the uterus, so that menstruation, as well as other modes of activity in the generative function, might determine an enlargement of the thyroid. Thus even diseases of the uterus and ovaries may be accompanied by bronchocele.

Of Mr. Tait's cases, the first occurred at Drymen, in 1863, the goitre first appearing at the fifth month of the first pregnancy. It went away after the first and the second pregnancy, but persisted after the third. In the fourth it grew rapidly and diminished slightly after the pregnancy terminated. Its renewed development later was the woman's first indication that she was pregnant for the fifth time. In all the other cases but one the goitre showed itself first during the first pregnancy. The locality is described as physically well situated, the ground gently undulating, with a deep subsoil of loose drift on porous sandstone. The drinking-water is from springs, or surface wells, except in the town, which uses river water, containing considerable lime, so that bladder calculi were common. The trade was wool-spinning. There was no goitre in this locality among men nor among non-parous women.

The latest contribution to this subject is in a thesis by Dr. A. De Burine.<sup>1</sup> After a general review of the subject he cites three cases, in all of which the goitre

\* Vulpian, loc. cit.

<sup>1</sup> Archives de Toxicologie, January 15, 1887.

seemed dependent on the act of parturition rather more than upon the condition of pregnancy. The cause for a bronchocele developing during labor is largely mechanical, and it seems probable that vascular stasis, passive congestion, amounting sometimes under the severe strain of labor to apoplexy of the gland, is essentially different in character from the hypertrophy above considered. The former phenomenon is merely mechanical, while the latter depends upon some as yet unknown physiological relation between the gland and the various epochs of the genetic function.

Dr. Burine gives three instances from his personal observation of goitre beginning at or near delivery in women who had no history of bronchocele either in their family or their neighborhood. The first was a woman, first pregnant at twenty. Gestation and delivery were both normal, but in the second week after confinement a small enlargement of the neck was noted. After each successive delivery (nine in all), the tumor gained in size though it remained without further growth during the pregnancies and the intervals between them. By the fifth pregnancy the tumor was one-half the size of a fist. In the fortnight succeeding the seventh confinement, the goitre rapidly increased to the size of the fist, and began now to cause dyspnoea. During the eighth labor the dyspnoea became urgent, and continued after delivery so that the nights were miserable. The ninth labor came on at seven months, after a gestation characterized by increasing dyspnoea. All work was impossible as was also the swallowing of food other than milk. During the labor the patient became asphyxiated and a dead child was delivered by forceps. The tumor at this time extended beneath the sterno-mastoid muscle on each side and from the supra-sternal notch above the hyoid bone. Despite the urgent symptoms the patient improved in her breathing a few days after the labor, and subsequently came to operation for the removal of the goitre.

A second patient passed through three pregnancies with no sign of goitre, but during the third labor she noticed a swelling of the neck and a tumor of the size of a walnut was left, which remained unchanged and caused no difficulty until she again became pregnant a year and a half later. Then at once attacks of dyspnoea and dysphagia began to occur, though the tumor did not further enlarge till the labor began. The labor was long, but despite an increase in the goitre there was no corresponding exaggeration of the symptoms. After the labor the tumor slightly diminished and then again remained stationary.

A third patient developed her earliest signs of goitre after her first labor at the age of twenty years and a half. It increased for the next six months, and underwent no further modifications in three subsequent labors at the ages of twenty-three, thirty, and thirty-two years.

It is to be hoped that further observations may throw light on the frequency of bronchocele in preg-

nancy, and the question whether the graver cases have some endemic character, as well as upon the general relations of the thyroid with the uterine glands.

#### RIGHT-HANDEDNESS. — II.

By a rather curious coincidence, an article on left-handedness appeared in *Science* practically simultaneously with the remarks on right-handedness in our issue of February 17th. The occasion for the former article was a paper by the learned Dr. Daniel Wilson in the "Proceedings of the Royal Society of Canada," in which he gives the weight of his support to Gratiolet's view that the cause of right-handedness is the greater development of the left side of the brain, and that, in left-handedness, the right side of the brain is preëminent.

The writer in *Science* endeavors to prove that what is now the cause of the preference for the right hand was originally an effect. For certain reasons, to be discussed presently, the right arm had attained preëminence, and this had reacted on the brain. This is a good instance of the quite independent reiteration of the same thing to which we alluded. We had written that, accepting the theory that the right arm is the strongest because it is used most, "there is no difficulty in supposing that the left side of the brain becomes more developed in consequence; and further, that these characteristics are inherited." So far we are at one with *Science*, assuming, for the moment, that it has been shown why the right side was originally the most used. The explanation suggested by *Science* is another of those jacks-in-the-box which it is hopeless to suppress. In short, it is that the warlike progenitors of the human race used the right arm for fighting and the left for protection, as they had perceived that wounds on the left were more dangerous. "Those who neglected this precaution would be most likely to be killed," and natural selection would do the rest. Nothing could be more simple!

There are, however, one or two criticisms we shall venture to make: We are told by *Science* that there is no right-handedness in lower animals, which is in direct contradiction to the well-known observations we mentioned. We would next ask: Are we seriously called upon to believe in the wound theory? What anatomical support is there for it? Two-thirds of the heart, to be sure, are to the left of the median line, and the left lung reaches a little farther down than the right. On the other hand, the superior vena cava is on the right; and so is almost the whole of that great reservoir of blood, the liver, which far more than counterbalances the left lobe of the liver and the spleen. Anatomists might dispute which side offers the greater danger to the attack of an enemy; but, according to our credulous writer in *Science*, not only did ignorant savages settle the matter, but, apparently, they had the same experience all over the world.

To show farther the childishness of such a theory, we must mention that, even in the warfare of primi-

tive faces, the opposing armies did not face each other like two companies of wooden soldiers, so that statistics could easily be collected to show the number and severity of wounds of either half of the body. They had a way of attacking from the side, or even from behind or obliquely; and, consequently, their weapons often pierced the foemen's bodies without the slightest regard to symmetry. There is reason to fear that severe, even fatal, wounds of the viscera on the left were inflicted by arrows entering on the right, and *vice versa*.

In view, therefore, of the great doubt whether there is any appreciable difference in the danger of wounds of the two sides of the body, and in view, also, of the deplorable irregularity with which we must suppose the wounds were given, we cannot accept this theory till we shall have had time to peruse the tabulated reports of pre-historic surgeon-generals.

This wound theory, as we have said before, is no new one, but we must give the ingenious writer in *Science* credit for an original explanation of the occasional occurrence of left-handedness. The survival of the fittest makes the race right-handed, "with occasional reversions, of course, by 'atavism,' to the left-handed; or, more properly, the ambidextrous condition." Now we well know that "atavism" is a very powerful *deus ex machinâ* to account for the unaccountable; but it passes our comprehension to see how the right-handed descendants of ambidextrous ancestors can become left-handed by atavism. Indeed, our author appears to have had his doubts about it, for he adds: "or, more properly, the ambidextrous condition." Very much more properly, we agree. But then the ambidextrous condition is not left-handedness, and the explanation appears to have melted away.

To return to the starting point, namely, Dr. Wilson's theory that the greater development of the left side of the brain is the cause of right-handedness, we can only say that the learned Professor appears to us simply to have changed the difficulty, for we agree fully with the implied criticism of *Science*, that there must be a cause for this greater cerebral growth; and further, we think it very likely that this cause is itself an effect, though we cannot accept the puerile theory that *Science* offers us to account for it.

#### THE BOSTON HEALTH REPORT FOR THE YEAR 1886.<sup>1</sup>

THERE were 9,268 deaths in Boston during the year 1886 as compared with 9,618 in 1885, 9,622 in 1884 and 9,740 in 1883. Guessing the population to have been 400,000, the estimated death-rate is put at 23.17 per thousand of the population, against 24.04 in 1885 with a State-census population of 390,393 in that year.

<sup>1</sup> Fifteenth Annual Report of the Board of Health, of the City of Boston, for the Year ending 1886. Boston: Rockwell and Churchill, 1887.

The number of deaths from "zymotic" diseases was 1,644 or 17.7 per cent. of the total mortality, and far less than in any previous year, the rates from 1885 to 1872 having been 19.5, 23.7, 26.2, 25.3, 26.9, 27.2, 26.2, 26.2, 25.9, 25.8, 29.6, 30.0, 24.3, 33.4, 34.9.

Diphtheria, which may be considered endemic in Boston, shows a falling off in the number of deaths, and a decrease yearly. The deaths reported during the year were 329; while the average for the five years previous was 436. The prevalence of scarlatina, for some years past, has been fast decreasing; the past year shows about half the number of deaths as compared with the year before, and with over 500 less reported cases. The percentage to the total mortality was 0.87, the number of deaths being 81. Typhoid fever shows a decrease of 17 deaths from the previous year, and the smallest number for any year during the past five years. Measles has comparatively the largest falling off in its mortality, the deaths being 40 per cent. less than those in the year 1885. There were 705 deaths from diarrheal diseases, a less number than in any year since 1870.

The total number of deaths of children under five years during the past year was 3,146, and, as compared with the previous year, shows a falling off of 248 deaths. It also shows a reduction of 384 as compared with 1884; and 441 from 1883, notwithstanding an increase in the population, and the least proportionate number of deaths of any year since the creation of the Board of Health.

There were 3,152 cases of infection-diseases reported, including only one from small-pox. The cases reported in the three previous years were 3,706, 4,487 and 3,718, a sufficient proportion to render measures of sanitary examination and control important and useful, but not enough to render statistics of cure-rates of any value.

The daily routine work of the Board is illustrated by the record of nuisances abated as follows:

House drains repaired . . . . .	2,802	Receptacles provided for garbage . . . . .	36
Vaults cleaned and repaired, 2,467		Passage-ways cleaned . . . . .	130
Traps supplied . . . . .	869	Stables put in order . . . . .	25
Yards cleaned . . . . .	545	Swine removed . . . . .	45
Stagnant water removed from vacant lots . . . . .	76	Sundry nuisances . . . . .	89
Water-closets repaired . . . . .	753	Manure removed . . . . .	75
Cellars cleaned . . . . .	653	Roofs repaired . . . . .	39
Cesspools cleaned . . . . .	299	Sheds cleaned . . . . .	48
Privies repaired . . . . .	93	Tenements whitewashed . . . . .	88
Vacant lots cleaned . . . . .	74	Supply-pipes repaired . . . . .	62
Fowls removed . . . . .	37	Goats removed . . . . .	2
General want of cleanliness of premises . . . . .	108	Dead rats removed . . . . .	21

The number of houses ordered to be vacated during the year was 148, of which number only 37 were actually vacated. The other houses having been put in proper condition before the expiration of the time specified in the notice, the tenants were allowed to remain.

There were 1,630 complaints examined in the usual way, and no cause for action was found.

We congratulate the Board on their having abolished 1,557 privy vaults in 1886 and 783 in 1885, and we regret to learn that the services of the Odorless Excavating Company were required to empty 3,853

within the limits of the city, during the year. There were 80,998 places disinfected in 1886, including 25,170 vaults and 13,732 cesspools. The number of rooms fumigated was 4,190.

Of 15 wells examined only 3 were found fit for use. At the abattoir 63,651 cattle were inspected, 22,308 calves and 449,465 sheep. Six calves and 4,189 pounds of beef were condemned.

At the public baths the record is of 714,514 baths for men and boys, and 194,886 for women and girls.

#### MEDICAL NOTES.

—The *Medical Press* publishes the following interesting extract from Mr. Greville's recently-published journal of "The Reign of Queen Victoria," vol. iii., p. 110: "I went, yesterday (1818), to St. George's Hospital, to see the chloroform tried. A boy, aged two and a half, was cut for a stone. He was put to sleep in a minute; the stone was so large, and the bladder so contracted, the operator could not get hold of it, and the operation lasted above twenty minutes. . . . A curious example was shown of what is called the *etiquette* of the profession. The operator could not extract the stone, so, at last, handed the instrument to Keate, who got hold of the stone; thereupon the first surgeon begged to have the forceps back, that he might draw it out, and it was transferred to him; but, in taking it, he let go the stone, and the whole thing had to be done over again. It was accomplished, but not, of course, without increasing the local inflammation and endangering the life of the child. I asked Keate why, when he had got hold of the stone, he did not draw it out. He said the other man's 'dignity' would have been hurt if he had not been allowed to complete what he had begun."

—The *Archives de Tocologie* quotes an interesting statement made by Rev. C. Wilson in "Uganda and the Egyptian Soudan," which seems to give some credibility to one of the theories regarding the determination of sex in offspring. After alluding to the predominance of females among the population as due in part to deaths among the males in battle and to the capture and bringing home of female slaves in war, he says that the children of Uganda women are not more generally of one sex than the other, but that the first births of women captured in war are largely females, in the proportion of 403 to 79 males. To the assumption that the more *able* of the parents determines the sex of the offspring to the opposite sex, this writer finds support in the fact that the men are happy in their victory and are cheered by feasts and drinking, while the women are depressed by sorrow at the defeat and death of their husbands and friends and the loss of their liberty. In the later pregnancies of these women, he adds, the proportion is changed to 100 boys to 137 girls. Again he says that the women of Central Africa, captured by slave hunters and carried along beside the train, if they become pregnant during their journey, usually give birth to girls.

#### BOSTON.

—The Committee on Public Health have reported to the Massachusetts Legislature, Senator Gleason, of Plymouth, and Mr. Bird, of Framingham, dissenting, a bill to regulate the practice of dentistry in the Commonwealth.

#### NEW YORK.

—Up to February 25th, ninety-two cases of small-pox have been reported during the present outbreak.

—For some time past diphtheria has been very prevalent in the vicinity of Fishkill-on-the-Hudson, and the mortality from the disease has been extremely large. In the last annual bulletin of the State Board of Health, the Hudson Valley District, which comprises all the counties, except Westchester, on either side of the river, is placed second in the State in mortality. For the entire State, the ratio per 1,000 deaths, from all zymotic diseases, to the total mortality for 1886, was 217.23, against 222.17 in 1885, and 269.12 in 1884. The conjoined death-rate per 1,000, from typhoid fever and diarrhoeal diseases, was 146.40 in 1884, 104.07 in 1885, and 94.44 in 1886, showing a continued reduction. On the other hand, diphtheria, which, it is claimed by the Board, is caused more by insanitary conditions of households, and is not so susceptible to public hygienic improvements, has prevailed more extensively; having had a death-rate, in 1884, of 47.65 per 1,000; of 56.06 in 1885; and of 64.48 in 1886. In each 1,000 deaths in the Hudson Valley District there were, in 1885, 62.63; and, in 1886, 64.63 from diphtheria. The total number of fatal cases in this district, last year, was 597.

—The King's County Supervisors have decided to build a new wing to the insane asylum, at Flatbush, which has so long been overcrowded, and have appropriated \$50,000 for the purpose.

—On February 22d, Professor Lancing gave a lecture on "Mummification," at Suydam Hall Chapel, New Brunswick, which belongs to the Rutgers' Theological Seminary; and afterwards, with the assistance of Dr. Van Vranken, of Albany, unwrapped a mummy in the presence of the audience. It was that of a royal priestess of the Nineteenth Dynasty, who lived about 1400 B. C., and was probably contemporaneous with Moses. The unwrapping occupied about two hours. There was, first, a layer of carefully-painted linen; and then hundreds of yards of narrow linen bandages, with an occasional sheet of linen, all the dressings smelling strongly of bitumen.

—During the past two years the experiment has been tried, in consequence of the large mortality that existed at the Randall's Island Nursery, of placing a number of the children from that institution under the care of nursing mothers, at their homes in and near Mount Vernon, Westchester County. The Commissioners of Charities and Correction now keep from fifty to sixty of them in the country, and the death-rate has been reduced among these infants from thirty per cent. to about five per cent. The cost *per capita* is \$13.50 a month, while at Randall's Island it is \$7.73. The

children are under the personal supervision of Dr. Robert T. Howe, of Mount Vernon; and, once a month, the paymaster from the City Comptroller's Department pays off the women at his office. Additional provision is also to be made at Randall's Island, where a pavilion adjoining the present buildings is to be erected, at a cost of \$25,000. This will accommodate from 1,500 to 2,000 adults and infants, and will relieve the present overcrowded condition of the Nursery.

### Miscellany.

#### THE BOSTON HERALD AND THE RAG QUESTION.

WE copy from the *Sunday Herald*, of February 27th, the following paragraph, and, in so doing, are not able to compliment our esteemed contemporary on its fairness, a fairness which we are accustomed to expect from it in other matters:

"The theories advanced by scientific authorities during the rag hearings last year, that contagious diseases are not carried by old rags, rather gets a setback by the discovery of four cases of small-pox among the rag-sorters of the Holyoke paper mills. How is this?"

In reply to the question, "How is this?" we would say that, to our knowledge, no such theories were "advanced." The fact was stated, and we repeat it now, that no case of cholera in this country had ever been clearly, or even presumably, traced to foreign rags in *bale*, as its source. The fact was also stated that small-pox had probably been conveyed in domestic rags, the very town of Holyoke having been instanced as an illustration of that statement; although it is, of course, not to be assumed that every case of small-pox occurring among rag-sorters is *ipse facto* evidence that the rags were the source of infection. There are among these rag-sorters many Canadian immigrants: out of a population of thirty thousand, eight thousand are French Canadians; moreover, small-pox has again been prevalent in the City of New York this winter, ninety-five cases having been reported to the health authorities up to Feb. 25th. We shall await further advices with reference to the source of the disease in these cases.

There was, previous to and during the rag hearings, last year, before the Committee of the Boston City Government, altogether too much of the sort of falsification and misrepresentation, of which the above is a specimen: it is creditable neither to interested individuals, to paid counsel, nor to newspapers reflecting their views.

### Correspondence.

#### PLAGIARISM OR TELEPATHY.

BOSTON, MASS., February 21, 1887.

MR. EDITOR,—Permit me to make use of your columns to call to the attention of those interested in psychical research a most remarkable instance of direct (or indirect) transference of ideas which has recently come to my notice. I received, a few days ago, a sample copy of the "Annals of Hygiene," the Official Organ of the State Board of Health of Pennsylvania, edited by Joseph F. Edwards, A.M., M.D., with an urgent appeal for a subscription.

On inspection of its pages I was much struck by the somewhat familiar appearance of many of the illustrations, which latter, according to an editorial in a former number which I have found, "we have decided to call to our aid to enable us to make clear the lessons of hygiene that we preach," for the very good reason that "that which is photographed upon the retina is much more lasting than that which is impressed upon the tympanum."

Referring to a little book published in London in 1881, called "Dangers to Health," by J. Pridgin Teale, M.A., I was surprised to find the exact counterparts of the illustrations to eight separate articles. Nor does the similarity stop here; the text of many of the eight articles is an almost exact reproduction of that in connection with the cuts in Mr. Teale's book. In the previous number already referred to, are four more illustrated articles, also counterparts of some of Teale's.

This, it seems to me, is one of those most extraordinary examples which cannot very well be explained by any theory of muscle-reading, since, as anybody will admit, the distance from Philadelphia to London is so great that even though the percipient were connected by wire—in this case the cable—the muscular impulses could not be of sufficient force to be of any assistance.

It would of course be highly disconcerting to even suppose that the editor took the articles and illustrations bodily from Teale's book, since in that event he doubtless would have given proper credit. Will somebody kindly explain? Yours very truly,

CHARLES HARRINGTON, M.D.

#### ON AXILLARY LUMPS.

ROXBURY, BOSTON, Feb. 21, 1887.

MR. EDITOR.—It is, of course, possible (as Dr. Boxall thinks) that I was wrong in the impression I formed from the scanty data at hand as to the similarity of Velpeau's five cases of axillary tumor to Champney's cases of axillary lumps. Dr. Boxall explains away very satisfactorily to himself all but one of the cases, that of Von Siebold, whose perfect resemblance to Johnson's case, and almost perfect resemblance to Champney's, even Dr. Boxall substantially admits; and, be it observed, if Siebold's case alone stands, Champney's claim of priority falls.

But now let us go a little deeper into this claim of Dr. Champney, and see where the question of the "Lumps," as a pathological entity, now stands. The facts in the case are these:

Dr. Champney read before an English Society a paper entitled "The Development of Mammary Functions by the Skin of Lying-in-Women." This memoir contains a report of some thirty cases of a peculiar kind of axillary tumor, believed by the author to be described for the first time in his paper, and all occurring in a single hospital in London. Having delineated their clinical features, he proceeds to speculate on their nature. He conceives them to be sebaceous tumors, and "to prove that in lying-in-women the sebaceous follicles of the skin are capable of producing true mammary secretions," also to "confirm the opinion that the breast is a highly specialized aggregation of highly specialized sebaceous follicles."

The paper ended, Dr. Pollock endorses the originality of Dr. Champney's observations, while Dr. Creighton expresses his belief "that the lumps or glands were not derived from sebaceous glands, but from another cutaneous structure," described by Sappey, Kölliker, and Frey, as well as by himself, in a paper before the same Society; in plain language, the axillary sweat-glands. Hereupon Dr. Champney changes his previous opinion and becomes "inclined to accept Dr. Creighton's view of the origin of these lumps." They differed, he said, from lipomata in the fact that they secreted milk.

Finally, on this side the water, comes Dr. Johnson, with

<sup>1</sup> See *Journal*, December 9, 1886, pp. 547-8; December 16, 1886, p. 583; February 10, 1887, p. 146.

an account of a case in his own practice, which he supposes to be either an axillary lymphangitis with lymphorhagia, a supernumerary mamma with lacteal secretion, or possibly a lipoma.

Now it did seem to me, Mr. Editor, that all this loose theorizing, by so many different gentlemen, was very unscientific and childish, and, moreover, failed to lend confirmation to the view either expressed or implied by all hands that they were dealing with a wholly new species of tumor. No man in these days can come forward as the discoverer, or even in a rigid sense, the describer, of a new tumor without a distinct demonstration of its pathological structure. It was the omission of such demonstration which I criticized, or intended to criticize, in Dr. Champney's investigation. Certainly it would not have been difficult for Dr. Champney, had he so chosen, to procure

some specimen, or cutting, or minutest possible shred of diseased tissue, for microscopic examination. In view of the uncleanliness and uncleanness of a constantly oozing tumor of the armpit, it would have been perfectly fair practice to lay open one or more of them, pack with lint, and at the same time excise a small portion for examination. Possibly a Duchenne's trocar, which is nearly painless, might have brought away tissue enough for the purpose, without any operation at all. Then we should have had exact knowledge in place of so many conflicting and valueless hypotheses.

The plain truth is, Dr. Champney's description is really no description at all. It is a description which does not describe. It is a conundrum still unsolved, and awaiting some new *Edipus* for an answer. Yours respectfully,

EDWARD T. WILLIAMS, M.D.

# REPORTED MORTALITY FOR THE WEEK ENDING FEBRUARY 19, 1887.

Deaths reported 2,055: under five years of age 788; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas and fevers) 326, consumption 362, acute lung diseases 350, diphtheria and croup 116, measles 80, diarrheal diseases 34, scarlet fever 22, typhoid fever 22, erysipelas 12, whooping-cough 11, cerebro-spinal meningitis nine, puerperal fever nine, malaria fever six, small-pox (New York) six. From scarlet fever, New York eight, Philadelphia and Pittsburgh, three each, District of Columbia two, Boston, Baltimore, Cleveland, Milwaukee, Providence and New Bedford one each. From typhoid fever, Philadelphia four, New York and Boston three each, Richmond and District of Columbia two each, Pittsburgh, Milwaukee, Providence, New Haven, Lowell, Lynn, Taunton and Fitchburg one each. From erysipelas, New York seven, Philadelphia two, Boston, Milwaukee and Fall River one each. From whooping-cough, New York three, Pittsburgh and Malden two each, Philadelphia, Richmond, Boston and Nashville one each. From cerebro-spinal meningitis, New York four, Lowell two, Philadelphia, Milwaukee and Fall River one each. From puerperal fever, New

York, Philadelphia, Baltimore, Cleveland, New Haven, Nashville, Lowell, New Bedford and Fitchburg, one each. From malarial fever, New York, Baltimore and District of Columbia, two each.

In the 20 cities and greater towns of Massachusetts, with a population of 930,404 (population of the State 1,941,465) the total death-rate for the week was 20.52 against 20.89 and 18.95 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,245,069, for the week ending February 5th, the death-rate was 19.6. Deaths reported 3,470: infants under one year of age 770; acute diseases of the respiratory organs (London), 279; whooping-cough 111, measles 104, scarlet fever 54, fever 40, diphtheria 29, diarrhoea 27, small-pox (Manchester and Blackburn one each), two.

The death-rates ranged from 13.5 in Nottingham to 28.4 in Plymouth; Birmingham 20.7; Bradford 23.3; Hull 18.6; Leeds 18.3; Leicester 18.6; Liverpool 20.8; London 18.4; Manchester 26.3; Newcastle-on-Tyne 21.9; Sheffield 20.8; Sunderland 19.3. In Edinburgh 17.6; Glasgow 23.8; Dublin 29.7.

The meteorological record for the week ending February 19, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending	Barom-eter.	Thermometer.		Relative Humidity.		Direction of Wind.		Velocity of Wind.		State of Weather. <sup>1</sup>		Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM FEBRUARY 19, 1887, TO FEBRUARY 25, 1887.

BABROWS, CHAS. C., first lieutenant and assistant surgeon. Resignation accepted by the President to take effect February 17, 1887. S. O. 42, A. G. O., February 9, 1887.

BLACK, CHAS. S., first lieutenant and assistant surgeon. Ordered from Fort Clark, Tex., to Fort Davis, Tex. S. O. 23, Department of Texas, February 18, 1887.

#### SOCIETY NOTICES.

MASSACHUSETTS MEDICAL SOCIETY, SUFFOLK DISTRICT.—THE SECTION FOR CLINICAL MEDICINE, PATHOLOGY AND HYGIENE will meet at 19 Boylston Place, on Wednesday, March 9th, at 7.45 o'clock. Papers: "A Case of Chronic Arsenic Poisoning of supposed Criminal Nature, with special Reference to the Medico-Legal Aspects," by Drs. Ernest Cushing and Morton Prince, Prof. E. S. Wood, and Drs. F. W. Draper, E. N. Whittier, L. F. Warner, of Boston, and Dr. A. F. Holt, of Cambridge, will take part in the discussion. Dr. Harold Williams, "A Case of Hodgkin's Disease." Dr. C. P. Putnam will open the discussion.

ALBERT N. BLODGETT, M.D., Secretary.

F. L. KNIGHT, M.D., Chairman.

BOSTON SOCIETY FOR MEDICAL OBSERVATION.—A regular meeting of the Boston Society for Medical Observation will be held at the Medical Library, 19 Boylston Place, on Monday evening, March 7th, at eight o'clock. Readers: Dr. H. C. Haven; Dr. E. D. Spear, "A Few Remarks about the Drum Membrane, with Cases."

CHARLES P. STRONG, M.D., Secretary.

GYNECOLOGICAL SOCIETY OF BOSTON.—The next meeting will be held at No. 19 Boylston Place, on Thursday, March 10th, at 4 o'clock, P. M. Paper: "The Truths of Nature demanding Similar Truths from Science and Art," by Dr. Horatio K. Bigelow of Leipzig.

H. J. HARRIMAN, M.D., Secretary.

#### DEATH.

Died in Charlestown, Mass., February 25, 1887, Jonas Angustus Marshall, M.D., M.M.S.S., formerly of Fitchburg.

#### BOOKS AND PAMPHLETS RECEIVED.

Fifteenth Annual Report of the Board of Health of the City of Boston for the Year 1886. Boston, 1887.

Eleventh Annual Report of the Boston Water Board for the Year ending December 31, 1886. Boston, 1887.

Follicular Amygdalitis. By A. Jacobi, M.D., President of the New York Academy of Medicine. New York, 1886. (Reprint.)

Vesical Irritation in Women. By Virgil O. Hardon, M.D., Lecturer on Operative Gynecology, Southern Medical College, Atlanta, Ga. 1886. (Reprint.)

The Census of Massachusetts: 1885. Prepared under the Direction of Carroll D. Wright, Chief of the Bureau of Statistics of Labor. Volume I. Population and Social Statistics. Part I. 1887.

On Fevers, their History, Etiology, Diagnosis, Prognosis and Treatment. By Alexander Collicie, M.D. (Aberd.) M.R.C.P., London, etc. With Colored Plates. Philadelphia: P. Blakiston, Son & Co. 1887.

Bibliographie des Sciences Médicales Index Methodique et Catalogue Descriptif des livres et Journaux Anciens et Modernes, français et étrangers sur les Sciences Médicales. Paris: Librairie J. B. Baillière et fils. 1887.

Refraction of the Eye: the Diagnosis and the Correction of its Errors. By A. Stanford Morton, M.D., F.R.C.S., Ed., Surgeon to the Royal South London Ophthalmic Hospital, etc. Third Edition. Philadelphia: P. Blakiston, Son & Co. 1886.

Novel Methods of Treating Diseases of the Middle Ear. By Seth S. Bishop, M.D., of Chicago, Attending Surgeon to the Illinois Charitable Eye and Ear Infirmary and to the South Side Free Dispensary, etc. Read at the Annual Meeting of the Illinois State Medical Society. Chicago, 1887.

Nervous Diseases and their Diagnoses: a Treatise upon the Phenomena produced by Diseases of the Nervous System, with Especial Reference to the Recognition of their Causes. By H. C. Wood, M.D., Ph.D., Member of the National Academy of Science. Philadelphia: J. B. Lippincott Co. 1887.

The Source of the Mississippi. Comprising I. Letter from Messrs. Ivison, Blakeman, Taylor & Company. II. Report of Hopedale Clarke, Chief of the U. S. B. T. & Co. Expedition to the Headwaters of the Mississippi, October, 1886. Ivison, Blakeman, Taylor & Company: New York and Chicago. (Reprint.)

Leçons sur les Maladies du Système nerveux faites à la Salpêtrière par J. M. Charcot, Professeur à la faculté de médecine de Paris, etc. Recueillies et publiées par MM. Babinski, Bernard Féry, Guinon, Marie et Gilles de la Tourette. Tome Troisième (Deuxième fascicule.) Paris. Aux Bureaux du Progrès Médical, 1887.

A Reference Handbook of the Medical Sciences, embracing the entire Range of Scientific and Practical Medicine and Allied Science. By Various Writers. Illustrated by chromolithographs and fine wood engravings. Edited by Albert H. Buck, M.D., New York City. Volume IV. New York: Wm. Wood & Co. 1887.

Diseases of Women: a Handbook for Physicians and Students. By Dr. F. Winckel, Professor of Gynecology and Director of the Royal University Clinic for Women in Munich. Authorized Translation by J. H. Williamson, M.D. Under the supervision and with an introduction by Theophilus Parvin, M.D., Philadelphia: P. Blakiston, Son & Co. 1887.

The Surgeon's Pocket Book: an Essay on the best Treatment of Wounded in War, especially adapted for the Public Medical Service. By Surgeon-Major J. H. Porter, Late Assistant Professor of Military Surgery, Army Medical School. Netley. Third Edition. Revised and Edited by Brigade-Surgeon C. H. Y. Godwin. Philadelphia: P. Blakiston, Son & Co. 1887.

## Original Articles.

THE RÔLE OF THE OVARY.<sup>1</sup>

BY SYMINGTON BROWN, M.D.

I ASSURE you, gentlemen, that I thought twice before adopting this title, — one which exposes me to a double cross-fire of criticism, and may possibly end in depriving me of the chance to perform any rôle myself in this learned Society. Let me hasten to explain that I do not mean anything disrespectful to the ovary. If this important organ only acts a part, what then? Do we do any more? And as I believe that it plays a leading part in the great drama of Life,—a part which men are only too glad to support in a subordinate rôle,—of course there can be no disrespect intended. This comes of introducing metaphysics into a gynecological society.

The minute studies of pathologists are often useful. I do not deny them; but it seems to me that pathological minutiae are like the scaffolding put up for the workmen during the erection of a building, intended to be removed when the building is finished. In fact, we cannot see the building in its fair proportions until the scaffolding has been removed.

In other words, I think that we have depended too much on morbid phenomena, and too little on the experiments which Nature kindly performs for us. More can be learned by careful observation of natural processes and guarded deductions therefrom, than from the twisted facts which disease presents us with. Naturally we cry up disease, for that is our business; but, I am happy to say, that the tendency in our day is to place more stress on the investigation of natural processes, so that we may be better able to recognize them when they become abnormal. We have hitherto put the cart before the horse, and our partial progress has been attained by pushing instead of drawing. It is on this account that I attach comparatively little importance to vivisections as a means of discovery. Experiments on living animals may corroborate or test a great disclosure; they seldom or never find one out. It is the recollection of what we have previously observed, passed through our mental alembic, which enables us to discriminate differences and recognize agreements. While I despise the senseless, sentimental outcry now being raised against vivisections, I think it is our duty not to overestimate them, and to make such experiments the exception, not the rule. Sir Charles Bell, in his classical work on the "Nervous System," asserts that if he had commenced with experiments, they would have misled him. He made his great discovery by means of dissections and clinical observations.

The extreme period during which the ovaries are active may be set down as forty years, say from twelve to fifty-two years of age. In the great majority of women, this period is limited to thirty years, say from sixteen to forty-six years of age. Before twelve and after fifty-two the possession of procreative power in women rarely exists; although a few recorded cases point to its possibility. Men may retain their virile power to extreme old age.

In childhood, the ovaries only contain microscopic ova; and after the menopause these organs become

atrophied, and all traces of germs finally disappear. In reproductive processes, nature seems to be ultra-generous. The number of ova in each ovary is out of proportion to the number of possible children. Many of these ova, no doubt, remain undeveloped; but even of those which reach the surface, and are capable of impregnation, how small a portion ever fulfil their function! Then, again, during each month there is a period during which the ovary is quiescent, and another period during which it is active. These may be called the cycles of involution and evolution. When the latter attains its maximum force, the ovary becomes nearly twice as large as at the close of involution, and is so sensitive to pressure that a tyro might conclude that it was inflamed.

Strictly speaking, the ovary is a gland which secretes free cells. It maintains an intimate connection with many other glands—a relationship more marked during pregnancy, but also noticeable during menstruation. More unsolved problems are probably connected with this relationship than is generally supposed. Jaundice, albuminuria, salivation, and mastodynia, may all be connected with, or dependent on, changes in the ovary. One reason why robust women (corresponding to the peasant class in Europe) recover more readily from puerperal diseases than pampered ladies, is the greater activity of the glandular system in that sort of patients. If we take puerperal albuminuria as an illustration, I think there need be no doubt that the affection does not arise from organic disease of the kidney, but is simply a functional disorder, following sympathetic changes in one or more of the reproductive organs. Anything which interferes with a single link of the chain affects the whole.

If we except syphilis, perhaps no other disease pursues a more insidious course, or fathers so many obscure symptoms, as gonorrhoea. Dr. Noeggerath, of New York, long ago directed our attention to this subject, and his assertions were generally met by the profession with almost scornful scepticism. I think that the sweeping verdict he passes upon commercial travellers is exaggerated; but the longer I live I meet with more and more cases which can only be satisfactorily explained on his theory—the existence of latent gonorrhoea.

When I was a medical student, in 1841, I asked our professors of anatomy and obstetrics, separately, this question, Why do prostitutes so seldom conceive? The answer from both was substantially the same; they said, they are driven beyond conception by their mode of life. For many years, I could get no better answer than this from anybody. But modern gynecology has demonstrated that the gonorrhoeal discharge passes from the vagina through the uterus and Fallopian tubes to the ovaries, and, exciting peritritine inflammation, is the true cause of sterility in prostitutes, and also, I am sorry to say, in many virtuous married women. Among the latter class especially this is not always preceded by an acute attack. The affection may be communicated by a mild, concealed gleet, which the husband himself is not cognizant of. As Dr. Noeggerath has pointed out, poisonous mucus may lie in a shallow cul-de-sac, near the bladder, and be discharged along with the semen, during coition, months or even years after the patient has seen any discharge at the meatus.

I suppose that bacteriologists, if they admit the premises, would explain the infection by the presence of

<sup>1</sup> Read before the Section of Obstetrics and Gynecology of the Suffolk District Medical Society, December 15, 1886.

a specific germ, which the attending physician had failed to dislodge. I do not express any opinion on that head. As the accommodating showman says: "You pays your money and you takes your choice." But whether caused by wicked germs or more ancient pathological processes, there can be no doubt about the widespread mischief resulting. The fibrous ovarian sheath becomes thickened, the Fallopian tubes are filled with muco-pus or closed, and it is highly probable that the ova themselves never become fully developed. If this happens to both ovaries or both oviducts, sterility is inevitable. We should also recollect that in many cases where the epididymis has been inflamed, spermatozoa are not to be found in the so-called semen, and the male is also sterile.

This brings us to the absorbing question, Should the ovaries ever be removed on account of metrorrhagia, salpingitis, long-continued agonizing pain or intractable pelvic disease? I refer, of course, to Battey's and Lawson Tait's operations. Many conservative physicians aver that removal of the ovaries unsexes a woman, changes her soft voice to a harsh, masculine tone, produces a beard and mustache, and takes away her sexual appetite. I believe that all, or nearly all, of these charges are baseless. We have good reason to conclude that sexual desire is not annulled within a period of at least four years after either operation. The only thing they annul is the ability to conceive; and, in our day, that is not reckoned much of a curse by many women. I am inclined to think that both the advocates and the opponents of female castration have been guilty of exaggeration. It is too true that the modern surgeon, like the American base-ballist, is apt to go to extremes. I have no doubt that some ovaries have been sacrificed which might and should have been saved, and I am also quite sure that many women have been left to drag out a miserable existence for years,—an opprobrium to the healing art, and a terror to their relatives,—who might have been spared untold mental and bodily suffering by a simple surgical operation, if the medical attendants had not been befogged by the ancient dogma of unsexing their patients. For sex is not lodged in either ovary or testicle: if in one part more than another, it is in the brain.

A long series of observations has convinced me that insanity in women often depends on sexual disorders, and, in such cases, can only be cured by treatment applied to the reproductive organs. The first case which impressed this conclusion on me occurred in Blackstone, Mass., in 1852. The patient was a young married woman, of Irish extraction, under the care of the late Dr. Kimball. She manifested signs of melancholic insanity, and attempted to commit suicide by striking her head with a dull hatchet in more than twenty places. We dressed her wounds, and got a neighbor to watch her, but on the second night she got out while the watcher dozed and drowned herself in the river. As it was a case for the coroner, we were allowed to make a post-mortem examination, and found inflammatory disease in the left ovary, with pus in the corresponding oviduct.

In cases of hystero-epilepsy, where the fits are prolonged and the mental powers are beginning to deteriorate, in consequence of ovarian disease, the best treatment is to perform Battey's operation. This is one of the grounds where even the most conservative gynecologists admit that the operation is justifiable.

It seems to me that in cases of long-continued severe pain, after the usual remedies have failed, we would be blameless if we removed the offending organs. There are other kinds of work besides childbearing which women can acceptably perform.

I have only seen one case where I thought that their removal was vindicable. The patient was an unmarried lady, about thirty years of age, who had suffered for several years from pelvic neuralgia so agonizing that latterly she had to give up work entirely. She was attended by Dr. Barss, of Malden, who called me in consultation. The operation was performed while I was absent in Europe, more than two years ago, and has proved successful. I learned recently that, although both ovaries were removed, she has menstruated regularly since the operation.

General practitioners are more interested in another class of patients, in whom the symptoms arise from suddenly-arrested menstruation, and there is no good ground for believing that the ovaries are seriously diseased; and yet, in the great majority of such patients, sterility results. A brief description of a typical case will illustrate what I mean. Five years ago I attended an unmarried lady, nineteen years of age, in whom menstruation was suddenly arrested by sea-bathing. Severe pelvic pain, sympathetic vertex headache, and a sense of constriction near the diaphragm, continued at intervals for a year, notwithstanding active treatment. Finally, she recovered, got married six months later, but has never become pregnant. To this day the diaphragmatic constriction remains, and the menstrual flow is gradually becoming scantier. Whether a sufficient degree of low-grade inflammation occurred to close the fimbriated extremities of both tubes, or, what is more probable, the nervous shock arrested the development of ova, I cannot say. Only this, that in all such cases I feel warranted in telling near relatives that sterility is highly probable.

I have only time left to state several questions relating to my subject, without attempting to discuss them. Is menstruation inseparably connected with ovulation? To give a correct answer, we should bear in mind that rare instances have occurred where three ovaries existed in one person; and also, that single ovaries may be abnormally implanted in the human parovarium, following the type of certain lower animals. In most cases, removal of the ovaries arrests menstruation within a few months. In Dr. H. R. Storer's celebrated Malden case, where he removed everything except an inch of the cervix uteri, the menses appeared eighteen days after the operation, lasting thirty hours, and were attended by the usual feeling of lassitude, backache, etc. The patient was forty-seven years old, unmarried, and had never conceived. The explanation seems to be, that the original menstrual impetus, in some cases, continues for a time after removal of the ovaries.

Negrier believes that the ovaries act alternately, one ovary active one month, perfecting ova, while the other is quiescent; the latter active next month. This somewhat fanciful theory receives a slight support from the circumstance that, when only one ovary is diseased, the pain sometimes returns every alternate month. Ovariectomy has decided one problem for us: it has proved that the sex of the fetus does not depend on the particular ovary which furnishes the germ; that is, that the right ovary does not furnish males, and the left females, exclusively, or *vice versa*.

Sir Spencer Wells tells us that ten patients, from each of whom he removed one ovary, afterwards conceived and bore children of both sexes. A woman with one ovary may even have twins of opposite sexes.

The proportion of male and female children born all over the world is so constant that we cannot help concluding that it must be regulated by a law as yet undiscovered. Here is a promising field for ambitious gynecologists. Whoever does make the discovery is as sure of fame as William Harvey. If I might be allowed to hazard a suggestion, it would be this,—that the determination of sex does not depend on anything done by either father or mother, but occurs long prior to conception in the ovary or testicle. That is to say, I believe that the agency which determines sex depends on peculiarities in the ova or spermatozoa, existing before coition.

One of the most interesting problems waiting solution is the sympathetic or metastatic affections connected with disease of the ovaries or uterus. Thus it is quite common for patients with ovarian disease to be troubled with intolerance of light, double vision, and some other eye-disorders. The same thing is often observed during pregnancy. Have we a correlation of diseases as well as one of forces? The first time that my attention was forcibly directed to this subject, strange to say, was among soldiers. In 1864, we had an epidemic of mumps in the 55th Regiment Massachusetts Volunteers, (colored), followed in eight or ten of the cases, by orchitis. The assistant surgeon thought that it was merely a coincidence, and I was at first inclined to concur with him; but soon became satisfied that the two diseases were more closely related. Dr. Goodell, of Philadelphia, has an article on "Inflammation of the Parotid Glands following Operations on the Female Genital Organs," in Volume X, Transactions of American Gynecological Society, which will amply repay perusal.

The only other example of sympathetic reaction I shall allude to to-night, is the increase of sexual desire in young women affected with phthisis. I have only seen one well-marked instance; but experienced medical friends say that they are convinced of its occurrence. What is the cause? Is it an illustration of the tendency of plants to run to seed when debilitated through a deficiency of nourishment? Does the fact throw any light on the greater fecundity of poor families as compared with rich ones? Perhaps some member will be kind enough to solve, or try to solve, these problems for us.

#### DERMATITIS VENENATA CAUSED BY LEUCANTHEMUM VULGARE.

BY JAMES S. HOWE, M.D.

LEUCANTHEMUM vulgare is the name of one of our common plants, which is known in different localities as white weed or field daisy. It is not indigenous in America, but was naturalized from Europe, being accidentally brought to this country by means of its seeds, which were mixed with those of other plants. It is most plentiful in New England, being still abundant in the Middle Atlantic States; and occurs more or less commonly all over the country, including Canada. It is spreading rapidly, and may be expected anywhere in cultivated lands. It is found throughout

the greater part of Europe, excepting in the extreme North and South, extending even to the Ural Mountains and Southwestern Siberia. It is not found in Portugal, Southern Spain, Sicily, Greece, Lapland, or Finland, and only in the southern parts of Norway and Sweden. Botanists say that the same limitations of distribution which exist in Europe will probably govern the spread of the plant in this country. Here in New England it is very abundant in the fields and meadows, being particularly noticeable during the months of June and July, when it is in full bloom. That it is capable of producing a very intense and troublesome form of dermatitis, and that this fact is not generally known to the profession, has induced me to present several cases of poisoning from this source which have come under my care.

My observations thus far have led me to suppose that it will prove harmful only to those who have a decided susceptibility to the poisonous effects of other plants. In fact, I can go so far as to say that I have yet to see a single case where the patient has not already had one or more attacks of dermatitis, caused by some of the well-known plants which produce the same results as the daisy. I am led to record these cases, not that I can add anything to our present knowledge of these forms of dermatitis and their treatment, but in the hopes of pointing out a source of dermatitis venenata, which, I believe, is not yet recognized by the profession at large.

CASE I. Mary B., aged six years. Two brothers and a sister of this little girl went out into the country, in the month of June, to a picnic; and gathered, while there, a large number of white daisies from the fields, and brought them home to their sister, who was confined to the house by some slight ailment. She was playing on the floor, minus her shoes and stockings, when the flowers were given to her; and remained there for half an hour, holding them in her lap and playing with them, as any child naturally would. The following morning her feet, legs, genitals, hands, and face were the seat of a severe dermatitis, with marked oedema of the legs below the knees, and also of the genitals. When I saw the case again, late in the afternoon, vesicles of small size, and closely aggregated, had formed in various-sized groups and patches upon the affected parts. These were accompanied by intense pruritus, and within the next twenty-four hours nearly all the vesicles had ruptured. This was followed by a gradual subsidence of all the troublesome symptoms, and also by excessive exfoliation of the skin; and, in about ten days, all the affected surfaces had returned to a normal condition. This child had been twice before poisoned by rhus, according to the mother's statement, neither attack being very severe; but it is doubtful if the child had handled the ivy so freely as she had the daisies.

CASE II. Willie D., aged five years. I saw this case in July, early one morning. I found a very marked efflorescence on the backs of the hands and between the fingers, with small, closely-aggregated vesicles in the latter position. What particularly attracted my attention was a well-defined band of a decided erythematous character, extending around the forehead and across the tips of the ears. Upon close inspection, I found this same region to be the seat of a very fine, papular rash, with here and there an already-formed vesicle, while the papules all showed a marked tendency to vesiculation. Upon the face and chin were also small patches of a fine, papular eruption, varying

in size and shape, and particularly marked upon the upper lip and the tip of the nose; also under the right eye, which was partly closed, owing to the oedematous condition of the lower lid. The only one of these patches where vesiculation had taken place was on the upper lip, which presented a condition closely allied to that of herpes labialis. On careful inquiry, I found that the child had, the day before, picked an armful of white daisies; and its mother had woven them into a wreath, which the child had worn upon its head for some time, with the above result.

Within twenty-four hours the fine papules on the forehead had nearly all changed to vesicles, presenting, in the form of a vesicular band, a very peculiar and unusual appearance. The mother was not poisoned, although I inspected her hands and face regularly for several days. She had never had any form of dermatitis resulting from poisonous plants, although, the year before, the child had suffered from a severe attack of a similar nature to this as regards symptoms, caused, as her physician told her, by ivy, although there is no proof that it might not have been caused by white weed.

This case yielded readily to treatment, excepting on the forehead, where, two weeks later, there was still decided redness and desquamation.

CASE III. Miss F. H., aged eighteen, had been poisoned by rhus a number of times when young, each succeeding attack being of less severity than its predecessor, until she had come to believe that ivy, so far as she was concerned, was comparatively harmless. While on a visit in the country she went out one morning to gather flowers in a garden, in one neglected corner of which was a large patch of white weed. After picking some flowers, the daisies attracted her attention; and she picked a basketful of them, and took them into the house and arranged them in a vase. That night she frequently awoke, always finding herself afflicted on the hands, forearms, and face with an intense burning and itching sensation, to relieve which she naturally scratched and rubbed the parts affected. The next day, when I saw her in the afternoon, there was a decided swelling of the hands and fingers, which, with the forearms and face, presented as complete a case of dermatitis as I ever saw.

Between all the fingers, and on the forearms, were many fine, closely-aggregated vesicles, the backs of the hands and face presenting only a fine, papular rash, with marked swelling and redness. The agony caused by the burning and itching was so marked, that the patient could only be kept quiet, and secure sleep, for three successive nights, by the use of opiates. The next day vesiculation took place inside the hands, beneath the thickened epidermis, both hands presenting the appearance to the sight and touch of a typical case of cheiro pompholyx. Relief was not long delayed, and desquamation followed in a few days. This patient rather doubted my statements when I told her that the white weed was the cause of all her trouble, and warned her, in the future, to carefully avoid it. The remembrance of her trouble kept her, the rest of that season, from making any further experiments with daisies; but the following year she again gathered some, with a similar result to the former one, only this time she escaped more luckily than before, all the symptoms being less severe than in the first case, although sufficiently so to call for active treatment.

CASE IV. I have, myself, been twice severely poi-

soned by white weed, the first case being the only one I had ever seen or heard of until I saw the one which is first described in this paper. As a boy, I had been often and very badly poisoned by ivy and dogwood, sometimes twice or three times in the same summer; hardly a season passing from my eighth to my sixteenth year without an attack, each of which was less severe than the former one. From my sixteenth year to the present time I have never been poisoned by dogwood or ivy, although I have often been in close proximity to them both, and even frequently brushed against them. Six years ago, while in the country, I gathered a large number of daisies, and carried them to the house where I was staying, never for a moment thinking what the result might be. That night I awoke, feeling upon my face and hands the most violent pruritus, and wondering what could have caused it; and such was its severity, that my sleep was very broken during the remainder of the night. In the morning I found that my hands and arms, as far up as the elbows, were covered with a very fine, papular eruption, the papules being arranged in groups of various sizes, while the entire surface was of a livid, angry-red color. My face revealed, on inspection, the same appearance, while both eyes were partly closed, the under and upper lids being oedematous. By evening of the same day the papules on my arms and hands had become vesicles, although it was another twenty-four hours before the vesicles appeared on my palms and the palmar surfaces of my fingers. The heat and itching was very troublesome, while my whole face was much swollen, feeling very hot and tense; and within forty-eight hours after exposure to the white weed, both eyes were so tightly closed that I could not see out of them at all. Strange to say, no vesicles appeared on my face, with the exception of a few on the chin. Sleep was only secured for several nights by the use of opium, until the acute symptoms had gradually subsided. Desquamation took place over the entire surface affected. The vesicles on the palmar surfaces, instead of rupturing externally, gradually coalesced, and the thickened skin came away in large stripes and patches, as is seen in so many cases of cheiro pompholyx. I had never heard of dermatitis before caused by daisies; and a physician who saw me at the time felt sure it was caused by rhus, although I insisted it was not, and could only attribute it to the white weed.

I have never touched a daisy since then until this past summer, being very careful to give them a wide berth. Last July, however, while out in the country, I passed through a field where there was some white weed; and, without thinking what I was doing, I caught the stem of one of the larger flowers between my second and third fingers, and snapped off the flower at the top. That night I awoke, and found myself scratching these two fingers, and immediately surmised the cause of pruritus. The next day, on the inner surfaces of these same fingers, was a group of fine vesicles, extending from the tip to the base of each finger; and rupture of the vesicles, with subsequent desquamation, was the result of this very mild attack. It is my rule now to warn all my patients with dermatitis caused by plants, to be very careful with regard to white weed; and, in the future, I expect to see more cases from this same source.

How many of the cases of dermatitis venenata attributed to rhus, dogwood, and sumach, may have

been really caused by white weed we shall never know; but, with an increased knowledge of poisonous plants, our diagnosis in the future will, of course, be more accurate.

## RECENT PROGRESS IN ANATOMY.

L. V. THOMAS DWIGHT, M.D.  
Parkman Professor of Anatomy in Harvard University.

### THE THIRD TROCHANTER.

THE occasional appearance of this process in man is familiar to all anatomists, but there are several questions connected with it that deserve study. One of these is in which sex it occurs most frequently. A discussion arose at a meeting of German anthropologists at Breslau in 1884, between Professors Albrecht and Török, the former maintaining that it appeared chiefly in females, which the latter was disposed to dispute. Albrecht had on his side a work on the subject by Dr. Houzé, of Brussels. The latter holds that the development of the third trochanter is in direct ratio to that of the gluteal region, which he says is more developed in Caucasians than in Africans, and in women than in men. Although he recognizes that fat has much to do with the formation of the nates, he seems to think that the muscles are also more developed in women. We must say, in parenthesis, that this is surely a mistake. Dr. Houzé found the third trochanter three times out of ten female femora, and only once among ten male ones, all from inhabitants of Brussels. This author describes a depression for the insertion of the gluteus maximus, which he calls the *fossa hypotrochanterica*. It is only occasionally present. This fossa is situated externally to the outer continuation of the *linea aspera*, between it and the outer margin of the bone which may be developed into a ridge. When this fossa is present the bone is usually broader than in other cases. This is an important observation, as showing how the same muscle may have very different surfaces for its attachment.

The gluteus maximus may be attached to a knob, a ridge, or a depression. Houzé examined bones of different periods, and found that bones unearthed in Belgium belonging to the reindeer period have rarely a third trochanter; but that it occurs in thirty-eight per cent. of those of neolithic times, and in thirty per cent. of to-day's inhabitants of Brussels. The converse is true of the *fossa hypotrochanterica*. In the reindeer times it was very common, less frequent in the neolithic era, and now very rare. We are indebted to the recent paper by Professor Török<sup>1</sup> for this account of Dr. Houzé's monograph. Török examined fifty-four skeletons, thirty-eight male, and sixteen female. He declares that the third trochanter is not most common in women, and that the fossa is not so rare in modern times. He found the third trochanter twenty-eight times in the seventy-six male thigh-bones, and eleven times among the thirty-two female ones, to wit: 36.81 and 34.32 per cent. respectively. He found the fossa in twenty-five femora, of which all but two were male ones. We would observe that while it is evident that Houzé's series are absurdly small to establish the relative frequency of the occurrence of this process in the two sexes, Török's are by no means sufficiently large.

Török makes the observation that while the great

and the small trochanters are each developed from an epiphysis of its own, the third trochanter is not. This brings us to the question, which we believe is quite a new one, whether every prominence at this point has the same significance. It is well known that some of the most striking instances of a third trochanter are found in delicate femora. In strong bones, with great rough lines for muscular insertions, more or less of a prominence is frequently found in the same place, but perhaps it may be questioned whether the former is not an instance of an analogy to lower animals (like the supra-condyloid process) and the latter merely an accidental elevation. Between these extremes all degrees are found. We have seen some examples of the third trochanter which it would be hard to believe did not arise from a separate centre of ossification, and Professor Török gives us no data showing how extensive his observations on this point may have been.

Our author concludes his paper with a table showing the relative frequency of the different forms of insertion of the gluteus maximus, namely, into a ridge, a depression, a tubercle (the third trochanter), and into combinations of these. The one hundred and eight cases were divided as follows.

#### SIMPLE INSERTIONS.

1. The ridge, — 25 male and 13 female bones.
2. The tubercle, — 4 male and 5 female bones.
3. The fossa, — 14 male and 1 female bone.

#### COMPLEX INSERTIONS.

4. The tubercle and the fossa, — 14 male and 1 female bones.
5. The tubercle and the ridge, — 10 male and 5 female bones.
6. The fossa and the ridge, — 9 male and 1 female bone.

In this connection we would mention an observation by Mr. Treves<sup>2</sup> of two remarkably-developed third trochanters observed during life on a man of fifty. "Following precisely the gluteal ridge of the femur was a bony outgrowth four inches in length. It was quite smooth, projected directly backwards, and appeared to be about one inch in height and half an inch in width. It was no wider at the base than at the free border; and this edge was perfectly distinct, even, and rounded. When the gluteus maximus was brought out into action, the fibres of the muscle were found to be inserted into this ridge, and during the contraction the free border of the bony mass was rendered indistinct. Both femora were marked by like projections, and the symmetry of the two abnormal ridges was in every respect complete."

#### THE DEVELOPMENT OF THE MASTOID PROCESS.<sup>3</sup>

Symington remarks that, while the anatomy of this part of the mastoid has been well worked up in the infant and the adult, but little attention has been paid to it in childhood. In fact, the mastoid process does not exist in the infant; but there is a cavity extending back from that of the tympanum. It is separated from the cranial cavity by a very thin plate of bone. The mastoid process becomes distinct at about the end of the first year; and the walls of the cavity become thicker and thicker, till, at puberty, a process of absorption begins, and the fine, cancellated tissue becomes cavernous. The mucous membrane, of course, makes its way into these cells. It is well known that the inside of the adult mastoid presents considerable diversities, which must depend on the process of absorption. The cavity in the mastoid is of about the same size in infants and in children, but in the latter it

<sup>2</sup> "The Mastoid Portion of the Temporal Bone," Edinburgh Medical Journal, October, 1886.

<sup>3</sup> Anatomisches Anzeiger I Jahrg. No. 7, September, 1886.

has much thicker walls. The author calls particular attention to a thick layer of fine, cancellated bone between the mastoid cavity and the lateral sinus, which, in childhood, keeps them well apart; but which, in the adult, may be changed into air-cells, some of which are separated from the sinus only by very delicate partitions.

#### THE SUPERCILIARY MUSCLE.

Heule, in his great work on anatomy, divides the *orbicularis palpebrarum* into three portions: The palpebral part proper, in the eyelids; the orbital part, around the margin of the orbit (in which he includes the so-called *corrugator supercilii*); and the malar portion, consisting of fibres from the outer and inner sides of the orbit, which converge as they descend, and end in loops or in the skin. Merkel<sup>4</sup> now proposes to further subdivide the *orbicularis*, and to make a superciliary muscle above the orbit, which shall correspond to the malar one below it. We should mention that Merkel does not recognize loops in the malar muscle, but represents it as of two convergent portions ending in the skin. To balance this, therefore, the superciliary muscle is divided into parts running upward and converging. The inner of these is our old friend, the *corrugator*; the outer is less distinctly defined.

#### THE PROSTATE MUSCLE.<sup>5</sup>

Mr. Reginald Harrison of Liverpool, has an idea of the prostate which certainly is not in accord with the usually accepted one. By the term "prostate muscle," he means the prostate itself, and apparently considers its glandular function as secondary to its work as a sphincter. He believes that, during life, the prostate never presents its post-mortem appearance of a hard body, of about the shape and size of a chestnut, excepting for the few moments when the bladder is completely empty. At other times, he holds that it is spread out like a funnel, supporting the bladder; the degree of expansion of the prostate varying, of course, with the distension of the bladder. Mr. Harrison goes on to say: "Hence the action of the prostate may be said to be just as continuous as that of the heart." Mr. Harrison invokes, in support of his views, the results of rectal examination when the bladder contains a certain amount of urine. If the shape of the prostate were what it is commonly supposed to be, one would find the greatest hardness and prominence in the median line; but Mr. Harrison points out that the centre of the prostatic area is softer and more yielding to the touch than the sides where there is a marked ridge presenting more or less tonicity.

#### THE UMBILICAL FASCIA.<sup>6</sup>

Richet called particular attention to this fascia in 1856-57, although its occasional appearance had been previously alluded to. He described it as a fibrous layer attached, at the sides, to the posterior sheath of the rectus, and having a superior concave edge a little above the inner aspect of the umbilicus. Between this and the *linea alba* ran his so-called umbilical canal, which, in its relation to umbilical hernia, he endeavored to make analogous to the inguinal canal. His views, in France, at least, received no great support. Tillaux finds the umbilical fascia of rare occurrence, and the canal an imagination.

Dr. W. Sachs, of Dorpat, has investigated the question anew, and has had the advantage of examining a large amount of material. He has studied the arrangement of the fascia in the first month of life and at later periods. He finds it no rarity at the earliest part of extra-uterine life. It was well marked in two-thirds of the children, ten days old or less, that he examined. It showed, however, much variation. The upper and lower borders were by no means always to be made out; and when they could be, it was far more common to find the lower border opposite or near the umbilicus than the superior one, as according to Richet. At the end of the first month the fascia and the peritoneum are, perhaps, more closely connected, but no important change has occurred. Sachs examined the bodies of 92 children who died during the first year of life; and found this fascia more or less clearly marked in 58, and wanting in 34. Of the 58, the fascia presented no definite boundaries in 33; the lower edge was sharp in 22, and the upper in only 3. In 35 cases the fascia ended above the umbilical ring, or close to it. It was well developed behind the ring in 23.

The outer coat of the bloodvessels, or what remains of it, is now converted into a number of cords; but, as the child grows, these become less and less important, and, for the most part, do little to support the umbilical ring. The relation of the umbilical fascia now becomes of consequence. If it be well developed directly behind the ring, it materially strengthens this weak point in the abdominal wall. If, on the other hand, the lower edge of the fascia is above or opposite the umbilicus, a pocket of peritoneum may pass under the edge of the fascia; and this form seems to be considered a predisposition to umbilical hernia.

#### METHODS OF PRESERVING THE BRAIN FOR DEMONSTRATION.

The first of these is recommended by Schwalbe<sup>7</sup> for making dry and hard preparations of the brain. The brain is first hardened in chloride of zinc, or in alcohol. After the removal of the pia, the necessary cuts are made, for this method is apparently applicable to parts of the brain, rather than to the whole organ. If chloride of zinc has been used, it is washed out with water; and then, in either case, the preparation, carefully supported, is put into strong alcohol. How long this is continued is not stated; but, as the object is to remove all water, it probably requires some time. We are told that, for whole hemispheres, it is desirable to change the alcohol often. The specimens are then transferred to turpentine, in which the larger ones remain for eight days, and the smaller for a shorter time. The next step is to thoroughly impregnate the pieces with paraffin. Schwalbe chooses a kind that melts at 45° to 50° C., and keeps the fluid paraffin in a hot-box, in which the temperature is kept at 60° C. The specimen remains in the paraffin-bath from five to eight days, after which it is taken out and allowed to dry, precautions being again taken to preserve the shape. Paraffin that melts at a higher temperature is likely to cause shrinking. The longer the preparations are kept in the paraffin, the darker they grow. The same paraffin may be used repeatedly, but it, unfortunately, grows darker. The specimens, when finished, are hardly at all shrunken, which seems to be the great merit of the method. They resemble paraffin models,

and can be cut into slices or dissected with a knife or a heated spatula.

The other method, devised by v. Lenhossack,<sup>1</sup> is likewise intended to prevent shrinking of the brain. It has the advantage over the other that it does not change the color, but the disadvantage that the specimen must be kept in alcohol. The brain is first hardened by any of the usual methods, alcohol, chloride of zinc, Müller's fluid, etc., but it is necessary that it should pass some time in alcohol before the special procedure is begun. This consists of painting the brain, which has been carefully and thoroughly dried, with a solution of medium thickness of celloidin dissolved in equal parts of alcohol and ether. This painting should be carried to the bottom of all the fissures, which should have been kept open during the hardening by cotton wool or filtering paper. This coating dries in a few minutes, and, as above stated, does not change the color of the brain, but gives a gloss to it. Though the brains must be kept in alcohol they may be removed from it and used for perhaps two hours without injury.

#### THE ANATOMY OF THE LIVING STOMACH.

The recent great progress in abdominal surgery calls for a kind of anatomical knowledge that is by no means general nor easily gained. Not only is it necessary for a surgeon to know the appearance of organs *in situ*, but he must know how they look during life. It may be questioned whether this can be thoroughly learned in any other way than by actual experience, but attention must now be paid to points of visceral anatomy that have been passed over as unimportant. This is well shown by the case reported by Dr. Meinhard Schmidt.<sup>2</sup> The essential points of the case are that for certain obscure symptoms, pointing to the stomach, he opened the abdomen of a woman of about forty. He was puzzled to find near the duodenum two distinct circular constrictions of the stomach. The one to the right was recognized as the pylorus, but the other, about one and a half finger-breadths from it, was more marked in its upper part, and almost as small. On the anterior surface of the pylorus he saw a patch of tendinous-looking tissue with radiating processes. As there had been a suspicion of ulceration in this region, and as it seemed not unlikely that this patch was the result of inflammatory changes at the base of the ulcer, an opening was made in the stomach and everything found perfectly healthy.<sup>3</sup> Dr. Schmidt points out that this tendinous appearance, though not constant, is normal, and is described by Heule. We give a few lines of the description which embraces another point of interest: "Two bands, the *ligamenta pylori*, are formed by the longitudinal muscular fibres, one on the front, the other on the hind side of the stomach, which (like the *ligamenta coli* to be described later) cause by their relative shortness the folding in of the other layers of the wall of the stomach which forms the entrance and exit of the *antrum pyloricum*. The tissue of the peritoneal coat is sometimes thickened over them, having a tendinous look and being richer in elastic fibres."

Professor Windle<sup>4</sup> has written a paper on "Sacculations of the Human Stomach," which concerns us in

this connection. Apart from constrictions due to pathological causes he finds that there are both temporary and permanent ones. Temporary ones are, of course, those due to the contraction of a part of the muscular coat, and we have no doubt that such occur, but we feel great hesitation in accepting, as temporary, some that Prof. Windle describes as such. He quotes a case reported by Struthers in which the stomach was examined the day after death, and presented a considerable contraction which resisted moderate distention with air for *several days*, till finally it yielded to greater force and no sign of the constriction remained. Surely we cannot suppose that a band of muscular fibres remained contracted for several days; and if we do not so suppose, why is it a case of temporary contraction? Prof. Windle admits that there are undoubted cases of permanent contraction making a reduplication of the stomach, and reports a case in which there were two such constrictions. We fully agree with him that the pouch, when there is but one, is sometimes at least only a high degree of separation of the *antrum pylori*. He holds also that there are intermediate stages between the antrum and this sacculations. For a description of the antrum we turn again to Heule. "The *antrum pyloricum* is separated from the rest, or the body, of the stomach by a constriction near the pylorus, which is more marked on the upper than at the lower border." Quain has the following passage in small type: "There is sometimes a distinct constriction near the pyloric end of the stomach, imperfectly separating it into two parts. This condition may be in great measure the result of local contraction of the muscular coat, but is occasionally of a more permanent character (Struthers.)"

Professor Windle refers to several authors who have written on this subject, but does not appear to be acquainted with the paper by Retzius,<sup>5</sup> to which Dr. Schmidt refers, and which is a very satisfactory one. It has no place, perhaps, in a report on *recent* progress, but none the less it deserves to be recalled to remembrance. The learned author discusses the *antrum* in man and in some of the lower animals. We shall refer only to his human observations, and to those very briefly. He finds that there are three classes of *antra*. The first is, perhaps, the more common one. It is bounded by the pylorus on one side and a constriction about one inch from it on the other. The second kind is a peculiar one. The pyloric end of the stomach is long and slender, so that it is sometimes mistaken for the duodenum. There may be two constrictions in the greater curvature and but one in the lesser. The third is the conical form.

### Therapeutical Memorandum.

#### "TEMPERANCE DRINKS."

ABSTRACT OF REPORT TO THE MASSACHUSETTS BOARD OF HEALTH BY THE BOARD'S ANALYST.

THE provisions of the Food and Drugs Acts of Massachusetts give authority to the State Board of Health to make inquiries as to the purity of drugs sold in the State, and also as to any other matters of a sanitary significance in connection with the subject. Much work has been accomplished and a better condi-

<sup>1</sup> Anatomischer Anzeiger. 11. Jahrgang No. 3, February, 1887.

<sup>3</sup> The patient made a good recovery.

<sup>4</sup> Proc. Birmingham Philosophical Society, Vol. I, Part 1, Session of 1885-6.

<sup>5</sup> Müller's Archiv., 1887.

tion of affairs secured in regard to the official or pharmacopoeial preparations.

Inquiry has also been made as to certain non-official, or empirical articles such as the so-called opium cures, all of which were shown to be grossly fraudulent; and also as to certain cosmetics of an actively injurious character. Further work has also been done in the examination of empirical tonics or bitters, with reference to the amount of alcohol contained in them.

Some of these are recommended as remedies for intemperance. The following report was recently made by the analyst of the State Board of Health, and the results obtained would seem to show that the inebriate would fare better by giving to all such nostrums a wide berth.

"Of the forty-seven following samples of proprietary tonics and bitters, I here give the detailed results of their assay for the percentage of alcohol contained, and the admissions of the presence of, or claims of the absence of alcohol, as given upon their labels and wrappers. The per cent. of alcohol is given by volume."

#### TONICS.

Carter's Physical Extract, Georgetown, Mass. Dose 1 teaspoonful, 3 times daily. 22 per cent.  
 Hooker's Wigwam Tonic, Haverhill, Mass. 1 tablespoonful, 3 times daily. 20.7 per cent.  
 Hoodland's German Tonic, Philadelphia. Admits Santa Cruz rum. Wineglass, 4 times daily. 29.3 per cent.  
 Hop Tonic, Grand Rapids, Mich. 1 tablespoonful to wineglass, 3 times daily. 7 per cent.  
 Howe's Arabian Tonic, New York. "Not a rum drink." Tablespoonful to wineglass, 4 times daily. 13.2 per cent.  
 Jackson's Golden Seal Tonic, Boston. Admits Marsala wine. Half wineglass 3 times daily. 19.6 per cent.  
 Liebig's Co's Coca Beef Tonic, New York. "With sherry." 3 teaspoonfuls to wineglass, 3 times daily. 23.2 per cent.  
 Mensman's Peptonized Beef Tonic, New York. "Contains spirit." 1 tablespoonful to 3, 3 times daily. 16.5 per cent.  
 Parker's Tonic, New York. "A purely vegetable extract," stimulus to the body without intoxicating. "Inebriates struggling to reform will find its tonic and sustaining influence on the nervous system a great help to their efforts." Dose as tonic 1 to 2 teaspoonfuls, 1 to 3 times daily. 41.6 per cent.  
 Schenk's Sea Weed Tonic, Philadelphia. "Distilled from sea weed after the same manner as Jamaica spirits is from sugar cane. It is therefore entirely harmless and free from the injurious properties of corn and rye whiskey." Dose, half wineglass, 3 times daily. 19.5 per cent.

#### BITTERS.

Atwood's Quinine Tonic Bitters, Boston. Dose, half tablespoon to wineglass, mixed with water, wine or spirit, 3 times daily. 29.2 per cent.  
 L. F. Atwood's Jaundice Bitters, Portland, Me. Half tablespoon to wineglass, 1 to 6 times daily. 22.3 per cent.  
 Moses Atwood's Jaundice Bitters, New York. Half tablespoon to wineglass, 1 to 6 times daily. 17.1 per cent.  
 H. Baxter's Mandrake Bitters, Burlington, Vt. 1 to 2 tablespoonfuls. 16.5 per cent.  
 Boker's Stomach Bitters, New York. Dose not given. 42.6 per cent.  
 Brown's Iron Bitters, Baltimore, Md. "Not a substitute for whiskey." Tablespoonful. 19.7 per cent.  
 Burdock Blood Bitters, Buffalo, N. Y. Teaspoonful to tablespoonful, 3 times daily. 25.2 per cent.  
 Carter's Scotch Bitters, Georgetown, Mass. Tablespoon to wineglassful. 17.6 per cent.

Colton's Bitters, Westfield, Mass. Teaspoon to 2 tablespoonfuls, 3 times daily. 27.1 per cent.  
 Copp's White Mountain Bitters, Manchester, N. H. "Not an alcoholic beverage." Wineglassful. 6 per cent.  
 Drake's Plantation Bitters, New York. "Contains St. Croix rum." Wineglassful, 3 times daily. 33.2 per cent.  
 Flink's Quaker's Bitters, Boston. Teaspoonful, 6 times daily. 21.4 per cent.  
 Goodhue's Bitters, Salem, Mass. Half wineglassful. 16.1 per cent.  
 Hartshorn's Bitters, Boston. Tablespoon to half wineglassful. 22.2 per cent.  
 Hoodland's German Bitters, Philadelphia. "Entirely vegetable and free from alcoholic stimulant." Tablespoonful, 4 times daily. 25.6 per cent.  
 Hop Bitters, Rochester, N. Y. 1 to 3 tablespoonfuls, 3 times daily. 12 per cent.  
 Hostetter's Stomach Bitters, Pittsburgh, Pa. Wineglassful, three times daily. 44.3 per cent.  
 Kaufmann's Sulphur Bitters, Boston. "Contains no alcohol." Tea to tablespoonful. It contains no sulphur, but has 20.5 per cent.  
 Kingsley's Iron Tonic, Northampton, Mass. 1 to 2 teaspoonfuls, 3 times daily. 14.9 per cent.  
 Langley's Bitters, Boston. Half wineglass or more, 3 times daily. 18.1 per cent.  
 Liverpool's Mexican Tonic Bitters, Boston. Half to full wineglassful, 3 times daily. 22.4 per cent.  
 Oxygenated Bitters, New York. Tea to tablespoonful. Acid but no alcohol.  
 Pierce's Indian Restoration Bitters, Boston. Up to wineglassful and to 6 times daily. 6.1 per cent.  
 L. Porter's Stomach Bitters, New York. Tablespoonful or more. 27.9 per cent.  
 Rush's Bitters, New York. Wineglassful, 4 times daily. 35 per cent.  
 Dr. Richardson's Concentrated Sherry Wine Bitters. Wakefield, Mass. Tablespoonful to half wineglass or more, 3 times daily, "or when there is sensation of weakness or uneasiness at the stomach. 47.5 per cent.  
 Secor's Cinchona Bitters, Providence, R. I. Half wineglassful, 3 times daily. 13.1 per cent.  
 Shonyo's German Bitters, Concord, N. H. Table to wineglassful. 21.5 per cent.  
 Job Sweet's Strengthening Bitters, New Bedford. Tablespoonful to wineglassful, 3 times daily. 29 per cent.  
 Thurston's Old Continental Bitters, Lynn, Mass. Tea to 2 tablespoonfuls. 11.4 per cent.  
 Walker's Vinegar Bitters, New York. "Free from all Alcoholic stimulants. Contains no spirit." Half to full wineglass. 6.1 per cent.  
 Warner's Safe Tonic Bitters, Rochester, N. Y. Table to wineglassful. 35.7 per cent.  
 Warren's Bilious Bitters, Boston. Teaspoon to 2 tablespoonfuls, 1 to 3 times daily. 21.5 per cent.  
 Wheeler's Tonic Sherry Wine Bitters, Boston. 2-3 wineglass, 2 times daily. 18.8 per cent.  
 Wheat Bitters, New York. Desert to wineglass, 3 times daily. 13.6 per cent.  
 Faith Whitcomb's Nerve Bitters, Boston. Tablespoonful, 3 times daily. 20.3 per cent.  
 Dr. Williams's Vegetable Jaundice Bitters, Lowell, Mass. Half to full wineglass, 1 times daily. 18.5 per cent.

### Clinical Memorandum.

#### THE AMBLYOPIA OF SQUINT.

BY O. F. WADSWORTH, M.D.

In the *Journal* of February 24th, Dr. Hasket Derby attempts to give a comparison of the vision found in his cases of convergent strabismus with that which I had given in a paper with the above title

(JOURNAL, January 20th). The attempt seems to have been not altogether successful. In the first place he says, "I rejected all cases of alternating strabismus." Why these cases, universally admitted to possess a higher degree of vision than the average, should have been thrown out, and then the remainder compared with my series, in which such cases were included, does not clearly appear. Then, a table based on this remainder, the class with highest vision having been eliminated, is given, which table does not show the amount of vision in the squinting eye, and we read, "By comparing these results with Dr. Wadsworth's a considerable difference will be at once apparent." No even approximately accurate comparison is possible under the circumstances.

There follows, "Deducting his [Dr. Wadsworth's] cases of alternating strabismus, he found vision equal in both eyes in 20.4 per cent., and 1 in only six per cent. of the cases." No statement of the number of cases with vision 1, is to be found in my paper. I said of my cases of convergent strabismus with vision precisely the same in each eye, "in seven of these (two alternate, one periodic),  $V. = \frac{1}{3}$  to  $\frac{1}{4}$ ." This gives, if the alternating cases are thrown out, 9.6 per cent., if both alternating and periodic cases are thrown out, 8.3 per cent. with vision *greater* than one. There was evidently an error in Dr. Derby's calculation.

The next sentences read: "Both he and Schweigger find thirty per cent. of their patients to have vision less than 1-7 (0.14) in the squinting eye. I find however, fifty-seven per cent. to come under this category. Out of my 160, 91 had vision less than 0.14 in the eye that converged. Moreover, half of Dr. Wadsworth's cases had, in the squinting eye, vision from 14-20 to 14-30; or putting it in decimals, of very nearly 0.5. I find only 11 per cent. (18 cases out of 160), to have this amount of vision."

In both these comparisons, with Schweigger's statistics and my own, Dr. Derby compares the vision of his cases of convergent strabismus, the alternating cases thrown out, with that of a series of cases which comprised both convergent and divergent strabismus, the alternating cases included. No wonder he found the results "startling."

I hasten, however, to fully acquit Dr. Derby of any intentional unfairness. Probably he was misled by his enthusiasm in defence of a theory in which he believed.

That there would be found a difference in the amount of vision in Dr. Derby's cases and my own, when properly compared, I think extremely probable. Such difference would naturally be found in the comparison of any two small series of cases. But I have already emphasized the importance of the greatest care in the determination of the vision of a squinting eye, and I believe that the comparatively high vision that I have found is in part due to the, perhaps from a practical point of view excessive, care and time that I have devoted to these cases.

That Dr. Derby should feel unable to explain the amblyopia of squint except on the suppression theory is perhaps explained by his statement in the discussion at the meeting of the New England Ophthalmological Society, that in his experience monocular amblyopia without visible cause and without squint is extremely rare. In my own experience it is by no means uncommon, and my experience does not stand alone in this regard.

In one respect at least, the effect of operation on vision, I am glad to find, there is no wide discrepancy between Dr. Derby's experience and my own views.

There is one other point on which a misunderstanding might possibly arise. I am quoted by Dr. Derby as observing with regard to cases of alternating strabismus "the suppression is not constant and therefore amblyopia does not result." For those who have read my paper explanation is unnecessary. The opinion quoted was not put forth as my own, but in the course of my statement of the views of those who, with Dr. Derby, believe in *amblyopia ex anopsia*. The very next line in my paper reads: "This is, I believe, a fair statement of the theory." And in the discussion at the meeting of the New England Ophthalmological Society I said that I thought it probable that in all cases of squint the squinting eye, at least when its amblyopia was not excessive, was occasionally brought into momentary use, but that I had employed the term "alternating" in its usual significance, that is, to denote only those cases in which the alternation was evident.

## Reports of Societies.

### SUFFOLK DISTRICT MEDICAL SOCIETY. SECTION OF OBSTETRICS AND GYNÆCOLOGY.

ROBERT B. DIXON, M.D., SECRETARY.

DECEMBER 15, 1886. DR. JAMES R. CHADWICK in the chair.

The proceedings opened with a discussion upon a paper read at a former meeting by DR. E. W. CUSHING, of which the following is a *résumé*.

#### EROSIONS OF THE CERVIX UTERI,

illustrated by microscopic preparation, and microphotographs as well as by photographs from life and from various authors, all of which were projected on a screen by means of a stereopticon.

First calling attention to the classifications of erosions by the older writers, he referred to the changes of opinion caused by modern microscopic research and to the mistakes made in not distinguishing post-mortem changes from pathological processes, and then referred to the labors of Ruge and Veit, not readily accessible to American practitioners.

The substance of the work of these authors shows that what are called erosions, ulcerations, etc., are various degrees of one process, which consists essentially in a new formation of glandular tissue, on the surface of the vaginal portion, or in the cervical canal.

The glands are formed by a reduplication, or sinking inwards, of the lowest layer of the cells of the rete malpighi, which are developed into a delicate cylindrical epithelium, forming a layer which everywhere lines the glands as well as the parts between them.

The latter forming partitions grow upward, while the glands grow downward, but still the projections are everywhere covered with a continuous layer of cylinder epithelium. The process goes on under the layer of flat epithelium which naturally covers the cervix, outside of the cervical canal; this layer is then lost, but no proper erosion occurs; what was formerly considered as such is a patch where the flat epithelium has been replaced by glandular formation.

The follicles and cysts are not usually enlargements of preëxisting ducts, but are newly formed glands without ducts. In ectropium there is essentially the same process going on in the cervical canal, thus everting the lips.

The above described active formation of glandular tissue may spread over the outer surface of the vaginal portion, where few, if any, glands normally exist; it may even extend to the vagina.

In exaggerated cases it resembles cancer so closely that the best experts cannot make a diagnosis without the aid of the microscope. In a comparatively large number of cases cancers of the cervix are preceded by this condition of gland-formation, or, to state it otherwise, these so-called erosions, when inveterate, not infrequently become cancerous.

A pathological condition of this kind, where normal tissues are wholly supplanted by new-formed glands is at best suspicious, and, considered pathologically, it is no wonder that it often serves as the starting-point of cancer.

These propositions Dr. Cushing proceeded to explain and demonstrate by some twenty slides and photographs, showing step by step the growth of the so-called erosions in virgin and parous and lacerated cervixes. The micro-photographs were mostly the work of Dr. M. Greely Parker, of Lowell, and were made by lamplight. The stained sections from which the micro-photographs were prepared, were made by Dr. Cushing in the Harvard laboratory. The photographs of patients etherized ready for operation, showed very clearly the appearances of erosions of various degrees as seen through the speculum.

In regard to ectropium in lacerated cervixes the reader stated that, if he understood Emmet aright, he thought the latter erred in considering the erosion as directly a consequence of the laceration of the cervix, in fact as only an exposure to sight of a not very abnormal cervical mucous membrane.

Dr. Cushing considers the process as just the opposite, that is, the mucous membrane becomes diseased from some cause not at present fully understood, but personally he believed the irritation to be due to some form of bacterial growth. Where there is a laceration, of course the cervical canal is more accessible, and more ready to take on diseased action, but without lacerations, and even in virgins, as previously shown, the same glandular endometritis goes on.

Where there is no laceration, the growth is more compressed, and spreads more or less evenly in a ring round the os uteri, actually supplanting the flat epithelium, normally clothing the vaginal portion. The condition of laceration permits of an eversion of the swollen lips rolled asunder by the thickened mucous membrane and the swelling glandular tissue and cysts. The latter, moreover, even go over on to the surface of the vaginal portion, sometimes even on to the vagina.

In the matter of treatment of erosion, the reader stated that everything depends on the condition of the uterus; for the erosions are merely to be considered as a symptom of a glandular endometritis, which has become visible, either by spreading beyond the normal limit of the cervical columnar epithelium or by everting a more or less patulous os, or by a combination of both processes.

For convenience the cases may be divided into:

(a) Those of so-called simple erosion, in virgins or

nullipare, associated with ante flexion of the uterus, or with stenosis of the os, or with elongation of the cervix, or with various combinations of these conditions, in most cases causing dysmenorrhœa.

(b) Erosions and endometritis of moderate degree, with subinvolution following parturition.

(c) Erosions with ectropium, as complications of a lacerated cervix; in either of the last two classes there may be a more or less complete rupture of the perineum; in any case there may be parametritis, salpingitis, adhesions, etc.

(d) Inveterate cases with induration of cervix and suspicion of commencing malignant degeneration.

In all these cases except in the second class, and provided there is no inflammatory trouble in the parametrium, the most satisfactory results are to be obtained by surgical measures. Even where parametritis, so-called, is present, with our present knowledge of salpingitis, we can frequently remove the whole focus of inflammation in the form of a diseased Fallopian tube.

The reader then described the medical treatment of the first form of cases, mentioning the good results obtained by the method of douches, dilations, tampons with cotton and boroglyceride, etc., with intra-uterine applications as elaborated by Dr. Wylie; but considered it rather a serious matter to condemn a virgin to such continued local treatment and advocated a thorough dilatation of the cervix, under ether, a curetting of the diseased endometrium, all under strict antiseptic precautions and sublimate irrigations; straightening the uterus if ante flexed with an intra-uterine stem, removing part of the cervix by the methods of Schroeder and Martin, if hypertrophied, and thus at once, without danger, if properly performed, doing more for the patient in an hour than can be done by months of local applications, more in fact than can usually be accomplished at all by the latter method.

In the second class of cases where after parturition, although there is little laceration of the cervix, the uterus remains subinvolved, with endometritis and erosions, Dr. Cushing believed that the subinvolution is caused by the endometritis, and not *vice versa*, that is, they are the result of a mild sepsis or bacterial infection; and precisely these cases when not too inveterate, are susceptible of cure by antiseptics, such as nitrate of silver, tincture of iodine, or strong carbolic acid. Of these the latter applied thoroughly on a cotton holder is the most effective. Of course, hot douches, ergot, strychnine, etc., may also be indicated. Even in old cases, where the uterus is enlarged and hardened, much good can be accomplished by this sort of treatment, but the results are usually not very satisfactory, and in the next class of cases, where there is cervical laceration the indications for surgical interference are even more imperative.

Nevertheless, where want of courage or opportunity, on the part of the patient, or a want of faith in surgical measures, on the part of the physician, exclude operative interference, the patient can be made comfortable, and with patience, apparently cured sometimes, even in cases of ectropium, by puncturing the cysts, scraping off as much of the glandular tissue as is possible under the influence of cocaine, and applying, at intervals, strong carbolic acid to the mucous membrane.

The dry treatment with iodoform and iron-cotton,

as used by Dr. Englemann, was described; also the use of strong, constant currents of electricity, by Dr. Apostoli, of Paris.

Nevertheless, Dr. Cushing thought it more scientific and satisfactory to give the patient ether, scrape out the uterus, after thorough disinfection; remove the glandular hypertrophy at once; repair the lacerations; make a good os, covered with flat epithelium; and thus cure the patient.

At the same time, if, as is very frequently the case, there is a rupture of the perineum, possibly complicated with cystocele or rectocele, the perineum can be repaired, and the appropriate colporaphy performed to remedy the other lesion.

How much more, then, in cases where there is any symptom of malignant degeneration of the erosions, is it the plain duty of the attendant physicians to recommend thorough removal of the suspected tissues?

The consensus of authority all over the world asserts that inveterate cervical erosions are peculiarly liable to cancerous degeneration; and every one who is in a position to see many cases of cancer of the cervix, knows that it is the saddest part of his mournful duty to tell the patient that it is "too late to remove it all."

In no one thing is a greater advance to be hoped for than in the early recognition and removal of whatever seems either malignant or doubtful; or so inveterate as to be likely to be an early stage of that most dreaded of all the ills to which the sex is subject, namely, a cancer of the womb.

Dr. Fitz, in opening the discussion, said that he had but little to add to the statement of the reader concerning the pathological changes which are to be found, as the basis of erosions. The investigations of Ruge and Veit had immediately attracted general attention, all the more readily, perhaps, from the repeated opposition of Fischel. The latter observer did not dispute the nature of the anatomical changes, but claimed a different method of origin. He regarded the erosions as an extension outwards of the cervical mucous membrane, and the replacement by it of the vaginal membrane. He subsequently discovered that, in a large fraction of new-born children, a physiological erosion was present; and assumed that the eroded cervix of the adult represented the exposure of depressions existing at birth, which had subsequently become covered with pavement epithelium. Unfortunately for this theory, the intervening stages have not been discovered. The occasional presence of ovula nabothi in the uterine lips is not to be regarded as the persistence of congenital conditions, but as the permanent remains of an erosion which has disappeared.

The use, by the reader, of the term glandular endometritis, as synonymous with erosion, seemed inappropriate. The former affection is usually considered to be limited to the body of the uterus; and to represent a simple hyperplasia of the normal constituents of the uterine mucous membrane. The erosion, on the other hand, is found in the vaginal portion of the cervix; is essentially vaginal, and represents the transformation of a normal tissue into one abnormal to the part. Cellular infiltration, vascular injection, and hemorrhages are common to both processes.

Two questions suggest themselves as important in connection with the future history of erosions: the one as to their cause, especially in virgins; and the other as to their relation to cancer. The former view,

that erosions were the result of the macerating effect of secretions flowing from the uterus, was no longer to be maintained.

The possibility of other causes than an endocervicitis or an endometritis was obvious, and clinical observations must be largely relied upon for their discovery. Dr. Fitz expressed a decided doubt, from the structural point of view, as to the importance of erosions in the etiology of cancer. The structure of cancer in various parts of the body simulates that of the epithelial surface with which it is in most intimate relation. Cancers of the body of the uterus are likely to be of the cylindrical-celled variety, while cancers of the cervix are usually pavement-celled. Were the latter the result of the inversion of an epithelial surface covered with cylindrical epithelium, which is admitted to be the method of production of the erosion, the resulting cancer, from all analogy, should prevent cells of a similar type.

Dr. Fitz desired to say another word with reference to the origin of cancers from erosions. It is the popular view that cancers are the result of local irritations, and popular views are not likely to be scientifically accurate. Like Dr. Chadwick, he had heard nothing this evening but opinions and beliefs concerning this relation; and, however valuable they might be, were still not to be regarded as evidence. The woman with a mammary tumor is sure to have been struck on the breast, or might have been injured there, if the cross-examination is sufficiently searching. Certain pipe-smokers have cancers of the lip; therefore, the irritation of the pipe-stem must be the cause. There were too many possibilities and uncertainties in the etiology of cancer for the recognition of local irritation as anything more than a possible cause. It was just as important to determine the number of cases of erosions not followed by cancer as to record those of cancer preceded by erosions. Pipe-smoking is much more prevalent than are cancers of the lip; and the latter may occur in persons unaccustomed to carry pipes, or even tooth-picks, in the mouth.

Dr. W. H. BAKER said that he considered erosion a cause of cancer of the cervix. In the majority of cases, cancer affects the lower part of the uterus, and in the majority of cases where there has been injury to the cervix. Undoubtedly, local irritation has considerable influence in the cause of cancer. It is important that the general practitioner should be able to recognize cancer of the cervix, for they see the cases generally before the specialist; and treatment, to be beneficial, should be given early. Erosions, even when slight, are important, and should be treated then and there; and, possibly, cancer might be obviated. In the cases of virgins, he did not agree with Dr. Cushing that it was best to apply operative measures early. These erosions are found in virgins suffering from constitutional disease; and, in these cases, more benefit would be derived from constitutional rather than local treatment, the latter being a shock to her, both nervously and physically. She can use, perhaps, hot-water injections and constitutional treatment; and if, after some months, these fail, then we should operate, instead of trying prolonged local treatment.

In cases of subinvolution without any decided laceration of the cervix, but erosion, one will get much benefit by operating. Both Dr. Seth Gordon, of Portland, and Dr. A. P. Dudley, of New York, have obtained

good results, by operating, in reducing the size of the uterus.

In cases of lacerated cervix, benefit from an operation is unquestionable. It is necessary to operate when the laceration extends beyond the crown of the cervix; and good may often, also, be obtained by operating where the tear does not extend to the crown, because the laceration intensifies the glandular secretion. He has seen, in a few virgin uteri, this condition, without any cause other than disease of the endometrium, which produced increased size and pouting out of the endometrium. An operation is needed in these cases; and, generally, one will give good results.

In the class of cases where there is beginning malignant disease, an operation should be performed. By so doing, life may be prolonged, and, possibly, the disease eradicated. The microscope should be used to decide whether all the disease has been removed.

DR. MARCY had little to offer except in commendation of Dr. Cushing's valuable paper.

Before Dr. Emmet had published his views, now so generally accepted, upon laceration of the cervix as the great fundamental cause of so-called erosions, Dr. Marcy had operated upon a case, diagnosed by several experts, as a probable epithelioma. There was a large mass of cellular proliferation which proved to be only glandular, and the removal was performed in a manner nearly identical with that of Dr. Martin, of Berlin, called after his name.

The turned-in vaginal flaps united perfectly, and later pregnancy supervened. The delivery was normal and the patient remains well.

Dr. Marcy repeated this operation successfully for a number of years, until he adopted that of Dr. Emmet as an improvement. However, in doing so, he underrated the factor of glandular hypertrophy, and had many partial failures because the removal was not thoroughly effected.

In 1876 Dr. Marcy accidentally saw the prize essay of Prof. Ercolani, of Bologna, upon the "Utricular Glands of the Uterus," and repeated many of the studies of this master. His other contributions upon this subject and its relation to the reproductive processes, were found in the Transactions of the Academy of Bologna, in the University Library, and translated for the benefit of the English readers; the second edition, enlarged, appeared in 1880, under the title of "The Histology and Pathology of Reproduction."

These studies brought clearly into prominence the importance of the glandular structures, not only of the endometrium, but also of the cervical canal. In their pathological changes are found many of the causes of dysmenorrhœa, leucorrhœa, of sterility, etc., which swell the long catalogue of woman's ills. He had for a considerable time believed the changes of circulation, innervation, nutrition caused by these growths, had much, probably more, to do as cause of epithelial cancerous development than the fact of pregnancy, or injury resulting therefrom.

The cause of this glandular hyperplasia is obscure. It certainly does not depend upon sexual activity or childbearing. It is not uncommonly met with in the virgin, and often in a very marked degree in the sterile, not seldom as a cause of sterility.

These enlarged glands can be reduced in their activity by the more ordinary means of treatment, hot water douches, tampons of glycerine, carbolio acid,

nitrate of silver, etc., but, when let alone, they usually take on increased activity. For a considerable period Dr. Marcy had operated surgically upon a large class of the severer forms of the disease, removing the hypertrophied glandular tissues and restoring the parts by modified plastic operation as seemed best suited to restore the parts to a normal condition. In no instance had he seen cause to regret so doing. These measures were in very large degree devoid of danger when done aseptically, a few days rest in bed, almost without suffering, gave a cure at once radical and effective.

Few subjects of a greater practical importance had been discussed before the Section, and our thanks were due to Dr. Cushing for his beautiful illustrations clearly showing a phase of disease certainly not generally recognized.

DR. C. M. GREEN said he could add nothing to what had been already said, except to emphasize the importance of thoroughly removing all hyperplastic tissue, in the operation for restoring a lacerated cervix, before closing in the cervix with sutures. Some operators make only a very superficial denudation; and although a shapely cervix may be the result, much cystic tissue is left which will be likely to cause trouble in the future.

DR. STROSG said that the operation proposed by Schroeder seemed to him the most perfect, theoretically, of any, for by it the whole mass of diseased gland tissue was removed; but there were some practical difficulties that make trouble in carrying out the details of the operation; first, it was impossible to slit the cervix up high enough to remove all the glands without the risk of involving the peritoneum or causing hæmorrhage; second, the stitch was almost certain to tear out at its upper part, near the os internum, as the parts were thrown together, as it could not be passed deeply. The speaker also alluded to the influence of laceration of the cervix in causing epithelioma, stating that in the large number of cases of malignant disease of the cervix that he had observed in his clinics at the Massachusetts General Hospital, and the Free Hospital for Women, not one occurred except where pregnancy had formerly existed. The experience of those present was asked upon this point, which seemed to the speaker an important one, as, if virgins are not predisposed to epithelioma as a consequence of erosions, much more time can fairly be given to an attempt to cure these by constitutional treatment, instead of at once adopting local measures.

DR. J. W. ELLIOT considered that erosions in the virgin were due to ill health. If erosions are found in the new-born child, why may they not be from congenital non-development? So far as operating goes Dr. Emmet's operation is not always applicable, but Dr. Schroeder's is more to the point. In virgins when the anterior lip rolls out he does not think the operation should roll in the diseased part, and removes a healthy wedge. He has operated on several virgins (?). He has seen three cases of cancer in virgins.

DR. J. R. CHADWICK said that he had for many years been familiar with the views as to the so-called erosions of the os to which Dr. Cushing had so ably drawn attention this evening. He had no doubt as to their correctness in a large proportion of cases, but had been unable to satisfy himself that every case was to be explained on the theory of glandular hypertrophy. He was still disposed to attribute a few of the

cases to simple erosion. These views were, however, based upon clinical and not upon histological researches.

He had never seen the *slightest evidence* that laceration of the cervix predisposes to the subsequent development of cancer. He had had in his practice quite a number of multiparous women affected with cancer. Dr. Fitz's statement, made this evening, that the common form of cancer, originating in the cervix is composed of such histological elements as to show that it does not develop from the glandular hypertrophy under discussion gives unexpected weight in opposition to the generally prevalent ideas to which Dr. Baker had just given expression. Dr. Chadwick consequently never recommends the repair of a lacerated cervix from any fear of subsequent malignant growth. The importance attributed to what has been hitherto known as erosions of the cervix has, in his opinion, been greatly exaggerated. He has never been able to connect any symptoms with this condition except leucorrhœa, and in rare cases hemorrhage, or local tenderness. He has never discovered any reflex phenomena, although he has sought them persistently. Retroversion, subinvolution, hypertrophy, congestion and all other conditions commonly attributed to the laceration, he thought much more naturally explained by referring them to the same cause as produced the laceration, namely, a difficult or unduly rapid labor.

Dr. W. SYMINGTON BROWN, of Stoneham, read, by invitation, a paper, entitled,

#### THE RÔLE OF THE OVARY.<sup>1</sup>

### THE NEW YORK ACADEMY OF MEDICINE.

STATED Meeting, February 3, 1887.

The President, Dr. A. JACOBI, delivered his

#### INAUGURAL ADDRESS

on entering upon a second term of office; and, in the course of it, alluded particularly to the successful working of the various Sections of the Academy, several of which are now in active operation; and to the urgent need of a new building, with more ample accommodations than the present hall.

#### A COMMITTEE ON BUILDING SITE

was appointed, which consisted of Dr. George A. Peters, Dr. F. A. Castle, and the President; representing, respectively, the Council, the Board of Trustees, and the Academy at large.

Dr. JOHN H. GIRDNER read a paper on

#### THE DETECTING AND LOCATING OF METALLIC MASSES IN THE HUMAN BODY BY THE INDUCTION-BALANCE AND THE TELEPHONIC PROBE.

The induction-balance, the invention of Prof. Alexander Graham Bell, first suggested itself, he said, in the summer of 1881, after the shooting of President Garfield. The attempt was made to locate the ball in his case by this means; but, owing to the crudity of the apparatus, the lack of experience in its use, and the disturbing element of a large steel mattress on which the patient lay — a fact unknown at the time — the result was unsatisfactory.

Dr. Girdner then proceeded to describe the apparatus,

which, he said, would be indispensable in time of war. An ordinary bichromate battery of six cells was used, and it was necessary that there should be an interrupted current; about six hundred interruptions per minute having proved the most useful for the purpose. For the induction-balance two currents were required, the primary and the secondary, or induced; and each current passed through two coils of wire, one of which was twice the size of the other. The larger coils were called the exploring coils, and the smaller ones the adjusting coils. The former, which were simply laid one upon the other, were secured to a large disc of wood, provided with a handle, which was called the *explorer*; and the coil of the induced current was connected with a telephonic receiver.

When no metallic substance was in the vicinity of the explorer, no sound whatever was heard by the ear placed at the telephonic receiver; but when the explorer was brought near a metallic mass, the presence of the latter was indicated to the ear by the sound heard in the receiver, this sound increasing in intensity as the explorer approached nearer and nearer the mass. The greatest intensity of sound was reached when the centre of the explorer approached the nearest to the metallic body. Fortunately for the successful application of the instrument, experiment had shown that living tissue was the best conductor of the sound.

The telephonic probe was also the invention of Professor Bell. A telephonic receiver was connected with a piece of steel laid upon the surface of the body, and also with a long needle, which was to be inserted into the flesh at the point indicated by the explorer as that at which the sound in the telephonic receiver of the induction-balance was most distinct. As soon as the point of the needle came in contact with the metallic mass, a sharp click was heard in the receiver.

Colonel Clayton, a gentleman who was shot in the breast at the Battle of Cedar Mountain, during the late war, and still retains the ball in his thorax, presented himself as a subject for illustrating the *modus operandi* of the induction-balance; and, by means of this apparatus, the location of the ball was readily determined to be at the junction of the clavicle with the sternum, although the scar of the wound made by the missile was at some distance. In order to demonstrate the working of the telephonic probe, Dr. Girdner employed a piece of beef, in which a mass of lead was deeply imbedded; and the experiment of detecting its precise location was entirely satisfactory to all who had the opportunity of personally testing the apparatus.

Dr. NEWTON M. SHAFER read a paper on

#### THE USE OF TRACTION IN THE TREATMENT OF CLUB-FOOT, WITH A CONSIDERATION OF SOME OF ITS MECHANICAL PRINCIPLES INVOLVED; AND A DESCRIPTION OF THE ANTERO-POSTERIOR AND LATERAL TRACTION APPARATUS.

He said that, more than ten years ago, he commenced a series of experiments in connection with the treatment of traction; and that the results of these early experiments were embodied in a paper which he had published in the autumn of 1878. This was, however, merely a professional paper; and since the time of its appearance, he had made many improvements in the apparatus he employed. Further experience had fully convinced him of the great importance of the "fresher" principle.

<sup>1</sup> See page 225 of this number of the Journal.

Dr. Shaffer illustrated the normal foot-movements by a series of diagrams. There was only one centre of antero-lateral rotation in the ankle-joint, he said; and this centre of motion was situated below the malleoli. In order to correct the deformity of talipes equinus, the heel must be made to move downwards and forwards, and the toes upward and backward. The neck of the astragalus rotates around the same centre of rotation as the heel and toes, and it rotates upward and backward. The normal movements of the foot should be exaggerated, on account of the resistance which is met with.

In the conventional clubfoot apparatus there were various defects. Thus, as the anterior part of the foot rotates upon its artificial ankle-joint centre, or, in other words, as we crowd the *os calcis* into the heel-cup, and attempt to flex the foot, the heel, unless restrained, slips forward. The attempt is made to control this movement by tying the heel down to the foot-plate, and in the heel-cup, with the heel-strap. If after this heel-strap is tied, a considerable pressure be applied in the direction of flexion (even, in many cases, after tenotomy), the further tendency of the heel (being restrained in front by the heel-strap), is to slip upward and backward away from its artificial annular ligament, ultimately, in many cases, resting on the top of the heel-plate which forms the cup. When this occurs, all control over the foot is lost, as it turns toward that side upon which the contractions exist. One of the direct effects of mechanical flexion, as applied in the customary forms of apparatus, to overcome either a post-tibial or a plantar contraction, is to crowd the tarsal bones together.

Dr. Shaffer then described his antero-posterior traction apparatus, by means of which, through the agency of a worm and screw, any desired angle of flexion or extension could be secured. The Scarpa heel-cup, which had been so long and universally employed, he said, was not necessary here, and a semi-circular opening was provided for the descent of the heel. In connection with the traction heel-strap, an astragalar strap was worn over a pad, and this astragalar strap was to be loosened in order to allow of rotation. When plantar contractions were to be overcome, however, the astragalar strap should not be loosened.

In equinovarus the lateral pushing force had many advantages over a lateral pulling force. The lateral traction apparatus, which he also described and exhibited, acted, he said, as a lateral pusher (everting the foot), brought the foot up into a position of flexion, and caused the anterior portion of the foot to rotate outward.

When we had to do with confirmed deformity, it was necessary that sufficient force should be used to overcome the resistance present, and he spoke of the great benefit which he had seen derived from the employment of *exaggerated* traction, maintained for a few seconds or minutes, according to the degree of tolerance present, and repeated at frequent intervals. In his experience, excoriations occurred only as the result of neglect on the part of the attendants. When the traction apparatus was used, the knife was unnecessary in many cases when it would ordinarily be required. There were, however, a certain number of rare cases which did not yield to simple traction, and in these tenotomy was demanded. In such instances, however, the patients were much more liable to complain of pain and discomfort from the wearing of the

apparatus, (after tenotomy), than in those which were treated by means of traction only. While there were a few cases which would not yield to traction, either with or without tenotomy, Dr. Shaffer said that he knew of no apparatus so efficient and complete as these traction shoes. In conclusion, he stated that nine years ago he had predicted that tenotomy would be much less frequently resorted to than formerly, and he was glad to say that this prediction had been verified.

Dr. RIDLON said that he had not been able to get as good results with the lateral shoe as Dr. Shaffer himself, who was remarkably skilful in applying his traction apparatus. Again, there were certain cases in which the use of traction was not followed with good results. We should be able, he thought, to judge at the beginning whether in any case traction would be beneficial or not, and the test of "point-pressure" enabled us to say whether or not tenotomy was called for. Dr. Shaffer, on the other hand, was in the habit of first trying stretching for a time, and then, if the result was not satisfactory, he performed tenotomy. It was better in his opinion to cut at once in those cases where the operation was required at all.

Dr. KETCH said that he had had an experience of over nine years with the traction shoe, and he desired to call attention to two points: (1) the possibility of treating many cases of club-foot without an operation of any kind, and (2) the fact that the benefit to be derived from the principle of the use of intermittent force, to the credit of the introduction of which Dr. Shaffer was entitled, was not sufficiently appreciated. As early as 1883, Dr. Shaffer had found that the danger of relapse after tenotomy was much less if the traction apparatus was employed.

Dr. A. B. JUDSON said it was clear that this apparatus of Dr. Shaffer was capable of exerting great force, and therefore it was especially necessary that it should be in careful hands. If, however, cases of club-foot were well managed from the first, this violence would not be required. By this he did not mean to reflect in any way upon the method of treatment described; but simply to refer to the desirability of an enlightened opinion in the community upon such subjects.

Dr. SHAFFER said that he was at a loss to understand the want of success in the use of the lateral shoe to which reference had been made. The application was simple, and it was only necessary that the shoe should accurately fit the deformity. The trouble was, he thought, that too much was attempted at first. The process of treatment must be a gradual one, with no haste and no violence. This method was a very easy one when the apparatus was properly adapted to the case, and just as much or as little power as was required, could be used with it. In regard to the matter of "point-pressure," he said that some of his best results with traction alone, had been obtained in cases in which this so-called test indicated tenotomy. For his part, he knew of no guide by means of which we could decide at first whether cutting would eventually be required or not.

—The *Annales de Gynécologie* which lost Dr. Courty from its editorial staff a year ago, has again been afflicted in the death of Dr. Gallard, one of its founders, physician at the Hotel Dieu, and one of the prominent gynecologists of France.

## NEW YORK NEUROLOGICAL SOCIETY.

STATED Meeting, February 1, 1887.

The President, DR. C. L. DANA, in the chair.

Dr. C. L. Dana reported a case of

**PACHYMENINGITIS HÆMORRHAGICA, WITH LARGE MENINGEAL HÆMORRHAGE PRESSING CHIEFLY ON LEG CENTRE; RIGHT HEMIPLEGIA, TOTAL PARALYSIS IN LEG, APHASIA, HEMI-ANÆSTHESIA, CONVULSIONS LIMITED TO ARM AND FACE. DEATH. EXHIBITION OF SPECIMEN.**

The patient was a woman about sixty-eight years old, and came into the hospital with complete motor aphasia, and unable to give any previous history. She had no paralysis at first, but three days after admission she had a general convulsion followed by right hemiplegia; total in the leg, and some right-sided anæsthesia; on the second and third days she had a series of brief localized convulsions involving the face bilaterally and the right arm. These were carefully observed. The movements were clonic, beginning in the muscles of the lower jaw. The other peculiarities were these: (1) The pupils remained small during the convulsions. When wider convulsive centres are discharging, as in general epileptic convulsions, the pupils are dilated. It is not probable that in this case there was some uræmic element, because the post-mortem disclosed a sufficient cause for them. (2) The conjugated deviation of the eyes was at first, and very temporarily, toward the side of the lesion, and away from the paralyzed side. The head also was turned toward this side. When this occurs, it is ordinarily spoken of as a paralytic deviation. This does not explain it here, since almost immediately the head and eyes were turned strongly to the opposite and paralyzed side.

The speaker suggested that the first deviation is due to an inhibition of the activity of the associated nuclei of the third and sixth nerves that innervate the external and internal recti of the two eyes. There are many facts which tend to show that the first stage of convulsion is a transient paralysis due to a sudden discharge of inhibition centres. These are of a higher, more developed class than the centres for motor discharges, and would be affected first. We would have, then, loss of consciousness, inhibition of motion and muscular relaxation; then motor discharges and tonic and clonic convulsions. (3) The temperature on the paralyzed side was one degree higher than normal and higher by a degree than that of the other side. This is the rule in intracerebral hemorrhage and hemiplegia, but the speaker was not aware that it has been established in cortical hemiplegias. In meningeal hemorrhages the temperature is often below normal, according to Minot. (4) The presence of hemianæsthesia.

The patient died on the third day. Post-mortem showed chronic pachymeningitis over both convexities, but more on the left side. On the left convexity there was a very extensive fresh meningeal clot pressing upon and flattening especially, the upper half of the central convolution. Brain substance normal.

**CORTICAL EPILEPSY WITH TEMPORARY APHASIA. SYPHILITIC GUMMA COMPRESSING THE LEFT SECOND FRONTAL CONVOLUTION IN ITS LOWER POSTERIOR PART. RECOVERY.**

DR. M. ALLEN STARR related the history of the

case. Charles S., aged thirty-two, had always been healthy and a hard worker. He had an attack of sciatica four years ago, and three years ago had a hard chancre. He had never had convulsions or nervous affection. Family history good. During November, 1886, and the first two weeks of December, he did not sleep well, was slightly dizzy, his head ached a good deal, chiefly at night. December 15th, while walking with a pail in his right hand, he suddenly let it drop, losing all power in the hand and arm. There was numbness in the hand. He was unable to speak to his companions. He did not feel dizzy or notice any pain in the head; he did not lose consciousness nor fall. He understood his friends' questions, but could not answer. Power in the hand and arm, and speech returned within half an hour. The next morning he went to work, as well as usual. Two days later a second attack occurred, beginning with a numb feeling in the tips of the fingers, gradually extending up the hand and arm. Then the fingers became rather forcibly flexed and stiff, but by a voluntary effort he could straighten them. No clonic spasms of the fingers, and wrist and elbow were not bent. The numbness and stiff feeling soon extended to the face, which was drawn to the right side with some force. Speech was again lost. No loss of consciousness. The attack lasted about twenty minutes. Such attacks had occurred every other day, then every day, and finally twice a day up to January 3d, and during this time the headache and insomnia were increasing steadily. The character of the attacks was not uniform. Sometimes the spasm would begin in the face, though usually the arm was first affected. Both were involved in every attack, but the spasm and numbness never reached the leg. The hand felt cold during the attack, though warm to the touch. On one occasion he had for four days great difficulty in making himself understood by words. Examination by Dr. Starr showed slight paresis, and slight tactile anæsthesia in right hand, no affection of face or speech. No cardiac symptoms. Though suffering from headache, percussion of skull did not reveal any tender spots. Thrombosis, endarteritis syphilitica, diffuse encephalitis with sclerosis were excluded, and the diagnosis was reached of gumma in the membranes, resting upon the brain surface, giving rise to irritation and consequently to an occasional nervous discharge, but not of sufficient size to cause any destruction. Location of tumor was equally clear: the relative situations of the cortical centres for the arm, face, and for the movements of speech in the lower two-thirds of the anterior central convolution and in the posterior part of the third frontal convolutions, were likened to a reversed L. All these centres were irritated during the attacks, the irritation sometimes beginning in one, sometimes in another. If the tumor pressed upon the lowest posterior part of the second frontal convolution, which would lie inside of the L, an irritation radiating from it might reach all three centres equally. The total intermission of the local symptoms might be explained by such a location since no symptoms were known to occur from injury of this part. The fact that numbness in the hand and face uniformly accompanied the attacks of spasm seemed to indicate that the areas for these parts coincide with the motor areas.

Another point of interest was the distinctly motor character of the aphasia.

The treatment ordered was first, inunction of mercury, and second, iodide of potash, daily in divided doses. He had one attack two days after beginning treatment, but since that time he had had no return of the symptoms. Iodide of potash was still being taken.

#### DISCUSSION ON DR. STARR'S PAPER.

DR. SEGUIN had seen several cases where symptoms resembled those of the case recorded in Dr. Starr's paper. The prognosis of even non-syphilitic cortical lesions with this symptomatology was not absolutely unfavorable. One of the cases to which he referred was that of a Cuban, who came to his clinic about nine years ago. He had never had syphilis, yet he described epileptic attacks of the true cortical kind, such as have been obtained by experiments upon animals during the last few years. The hand would become numb, and then the seat of a vibratory sensation; finally contraction would occur in the hand, then the face, and almost simultaneously the leg, would be affected, and he would lose consciousness. According to his friends' account general convulsions then occurred. He had had quite a number of these seizures, yet examination showed no anesthesia, no affection of the optic nerve, and so far as the speaker could recollect, no motor impairment. The patient had received a preparation composed mostly of the bromide of potassium to which a little of the iodide was added. He improved immediately, and four years ago the attacks ceased. Once in a while he has the sensation of wires in the hand, and the hand becomes stiff, but the face is never affected. The case was a beautiful illustration of the localization of a lesion in the centers for the hand, the discharge radiating to those of the face and leg of the same side, then to the opposite side, with loss of consciousness.

The patient had also been the object of the bracelet experiment. He was a powerful man, and had exerted great force, arresting many attacks in this way. The speaker was satisfied that syphilis was absent, while the amount of the iodide was too small to explain a cure upon the ground of a syphilitic affection.

DR. STARR had been much interested in the case which Dr. Seguin had related. He had recently had a case of unilateral convulsions in his office. The patient was a small boy. The attack commenced in the eyes and face. The eyes turned to the right, then the head turned to the right, then the arm, then the leg became affected. During the attack the speaker had asked suddenly, "What is your name?" the boy promptly replied, "Arthur," and then relapsed into the convulsion. He supposed that the reply was reflex, as the boy was unconscious at the time and did not afterward remember the occurrence. He would like the opinion of the members upon the point.

DR. DANA asked what Dr. Seguin had considered the lesion in his case.

DR. SEGUIN had never ventured to surmise, beyond the fact that there was a nerve lesion and that there was no syphilis in the case.

DR. STARR asked Dr. Seguin whether in localized convulsions numbness were not the rule.

DR. SEGUIN replied that it was, but he did not know that the reason was yet sufficiently established, although Von Monakow had associated anesthesia with lesions of the motor zone.

DR. SHAW referred to a case seen first four years ago. While at work as a jeweler the patient fell off

his bench in a convulsion. The face and the left arm were convulsed; the leg was not affected. Sometimes only the side of the face was affected. He had seen many of these attacks limited to the side of the face in his office. The patient complained of numbness in the arm and the side of the face. And the speaker felt sure that the tactile sensibility was not as good upon that as upon the other side. The patient denied syphilis. Upon ophthalmoscopic examination the nerves were found pale, and the visual field restricted in its upper part. There was no change until about six months ago, when, without loss of vision, he was found to have choked disk. This had gone on to atrophy, and the man was now blind. There was no paralysis. From the choked disk of course the speaker had now diagnosed a tumor, but he referred to the case on account of the anesthesia and the spasms, and their resemblance to those in Dr. Starr's case.

DR. SACHS referred to the case of a man who, some years ago, while working upon the capitol at Albany had fallen some distance, was found unconscious, but recovered. A few weeks later he developed symptoms which alarmed his friends, and he had now some of the physical and nearly all of the mental signs of general paresis, — the irregular pupils, the facial tremor, the tremor of the tongue, and the deteriorated mentality. The speaker referred to the case because of the traumatic incident, and because every three or four weeks this man had an attack of numbness beginning in the fingers and creeping up the right arm to the face. There never were convulsions, but both the patient and his wife, who is a very intelligent person, say that there is paralysis. After three or four hours both the paresis and the numbness disappeared, and he has a very severe headache, lasting one or two days. The speaker thought there was a question of chronic meningitis with encephalitis possibly in this case. It was evidently a cortical affair.

DR. DANA thought that cortical epilepsy might develop like idiopathic epilepsy without an appreciable lesion. He recalled a case, that of a young man who was kicked in the front of the thigh by a horse. Twitching of the leg developed, similar to that of cortical epilepsy. Thrilling and numbness of the arm and face followed. In a year true hemiepileptic attacks, during which he lost consciousness, developed, and, upon giving him ether for stretching the nerve he went into the status epilepticus. There was no history of syphilis. Apparently cortical epilepsy was developed, just as true idiopathic epilepsy in other cases.

(To be continued.)

— The *Northwestern Lancet* (St. Paul) contrives to get in a sharp rap at a sister city, in acknowledging the first number of a new medical journal published at Chicago, by saying that "there is no city in the country where there is more room for good medical journals than in Chicago."

— At the end of the year 1885-86, the number of cinchona plants on the four Madras plantations of the British Government was nearly 2,000,000, while those of the Bengal Government, at Sikkim, number nearly 5,000,000. The former plantations produced, in the year, 113,300 pounds, and the latter 339,201 pounds. The profits have been so great that private enterprise is beginning to be attracted to the business.

### IODOFORM NOT AN ANTISEPTIC.

THE universal use of this drug, and the satisfactory results obtained, especially in operative surgery, have inspired great confidence in its power to arrest the development of the omnipresent, much-dreaded germ, and to ward off septic infection, with its attendant disastrous consequences. But this confidence has been dealt a staggering blow by the results of an investigation recently completed, the object of which was to determine the true value of iodoform for this purpose.

Although, perhaps, a suspicion of the real truth may still be the incentive to the series of experiments, still the results obtained must have formed a most startling and unexpected conclusion to the work of the investigators.

Iodoform, during the past few years, has held a position second only to sublimate and carbolic acid. It has been used externally and internally. It has been powdered on surfaces; injected in solution into cavities; or employed in the antiseptic covering of injuries and operation wounds, as the agent which was to hold in check the development of septic processes.

This wide-spread use of the drug in modern surgery as a germicide, or (according to the more generally accepted theory) as a substance which effectually prevented germ development, either by the liberation of free iodine,<sup>1</sup> or the formation of iodides;<sup>2</sup> and also the scanty authentic proof, by actual experiment, of its real antiseptic power, recently attracted the attention of MM. Heyn and Rovsing, of Copenhagen. A review of the work, already published, soon showed that the reputation of iodoform rested mainly on clinical data, the only real work on record being represented by the indefinite results of Kouig,<sup>3</sup> Mikulicz,<sup>4</sup> Rammo,<sup>5</sup> and Meyer.

This, and the knowledge that the clinical evidence

was not wholly trustworthy, since iodoform is rarely used without other antiseptics of known value (carbolic acid, thymol sublimate, usually in solutions for irrigation), led to an investigation,<sup>6</sup> the results of which have recently been made public. In a series of plate-cultures, iodoform appeared to have no power in retarding the growth of the *staphylococcus aureus pyogenes* or *bacillus subtilis*. Various experiments with a mixture of sterilized gelatine and iodoform, with iodoform and olive oil (four per cent.), and a solution of iodoform in blood-serum, showed an unchecked growth of the above-mentioned germs in these media. It was found that the *staphylococcus aureus pyogenes* preserved its vitality, at least a month in dry iodoform powder; and experiments on rabbits, where inoculated fluids were prepared with iodoform, gave similar results.

The above data, it is claimed, show that iodoform, no matter how many other excellent properties it possesses, is, as an antiseptic in surgery, valueless. It is also a dangerous substance, since there is a possibility that the drug itself may even contain pathogenic organisms; and that, even if it can itself be kept aseptic, it does not destroy or prevent the development of microorganisms, which may obtain access to a wound with it, as, for example, when it is applied with an unclean brush or spatula, or introduced by a spray. The full details of the experiments accompany the original publication of the experimenters, who recommend that iodoform, if used where aseptic conditions are necessary, should be disinfected with sublimate as carefully and thoroughly as sutures, ligatures, or instruments.

Johan Olsen's<sup>7</sup> investigations with reference to the influence of iodoform on the bacillus of osteomyelitis (*staphylococcus aureus pyogenes*?) confirm the above results.

It is unnecessary to comment on the value of such results, if true; and their importance to the surgeon and his patients demands an immediate confirmation or refutation of such statements. This may prove to be another instance where a substance, whose reputation rests on clinical evidence, not corroborated by the results of scientific investigation, has really a certain empirical value. But, however this may be, the attention of bacteriologists cannot be too forcibly called to the necessity of an early investigation of this subject; for, if the conclusions noted be confirmed, lives of patients are daily exposed to an unknown danger, since, with the same drug, on which the surgeon relies most to protect the patient from the dreaded germ, he introduces into a wound the very elements of septic invasion he seeks so anxiously to shun. His most trusted ally proves to be not only inert to destroy the enemy, but even the disguise under which the latter enters unseen and unsuspected; and again, through a sense of false security, the employment of other means by which dangers might be avoided are neglected.

## THE EXTRA-ASYLUM DEPENDENT INSANE.

## I. THE BOARDED-OUT INSANE.

IN the Eighth Annual Report of the Massachusetts Board of Lunacy and Charity there is much matter for reflection and scrutiny on the part of the medical profession. It concerns the present and future welfare, more particularly of the dependent insane of our State, cities, and towns who are not under asylum protection, treatment, and care. To consider, first, the lot of a few of this class, whose condition, we may safely say at least for the present, is a matter for congratulation, let us turn to the progress of an innovation, in this country, in the way of providing for certain of the chronic insane.

It is now a year and a half since the system of providing for properly-selected cases of chronic insanity, under official supervision in families, went into operation in this State: and, although a much longer trial is needed before its success can be considered established, it has, at least, been proven, by actual practice, that the employment of the "Family System" of caring for this class of the insane may be under proper conditions, as practicable and beneficial in its results in this State and country as it is to-day in Scotland and Belgium. If the scheme should fail, therefore, its failure would probably be due rather to improper management, than to any fault inherent in the system itself.

The objection to this method which is generally urged has been found, it seems, to have the least foundation in fact. It has been thought by some of the least sceptical among the many opponents of the system, that the difficulty of finding families who would consent to receive a lunatic among them, on any consideration, would be a great obstacle in itself; that such as might be willing to make the experiment would not be suitable; and that, finally, the pittance of \$3.25 a week would deter desirable families from even considering the proposition. The experience of those in charge of the boarded-out patients apparently disposes of this objection, and is strikingly similar to that of the Commissioners in Lunacy in Scotland, where the system has long been a flourishing and useful one. As stated in the Report of the Massachusetts Board: "Applications from families in every way suitable have been made — enough to furnish places for twice as many patients as we could send. These families generally live in the rural towns, and are those of mechanics or farmers who are living comfortably; and, although the rate is low for villages, it is sufficient in the farming towns."

Another objection to the system, and a natural one, is suggested by the danger of abuse and neglect of patients so situated. That this fear also is exaggerated appears from the fact previously observed in Scotland, that "it is the almost universal wish of these patients to remain where they are, rather than to go back to the hospital from which they were taken."

That the number of these patients has been small — somewhat over sixty — is apparently due, in a mea-

sure, to a commendable caution in pushing an untried enterprise, as well as to the opposition of various municipal authorities limiting its scope to State patients taken from the State Hospital or from the Tewksbury Asylum. Quite a large number, therefore, who are dependent upon their respective towns for their support, are deprived of the advantages of this kind of care. Should the measure prove to be all that is hoped for, physicians can do good work for the insane by impressing upon their city or town authorities the advantages of this provision for their insane charges now in asylums and almshouses.

The value of this new provision for the insane, now in active operation for the first time in this country, will be judged by the results in this State, and it is to be hoped that experience will warrant the extension of the system to its full limits.

If the system be rightly conducted, its general adoption in this and other States is probable, but regular and frequent visitation of the patients by competent medical and other officials is an important element. The Scottish department owes its results to a board of paid commissioners, the active work in this department devolving upon medical men trained by actual experience as superintendents of asylums. The Board of Lunacy and Charity seems to be alive to the vital necessity of proper supervision; nevertheless the recent legislation in this direction is faulty in not requiring visitation by a medical man of practical experience in the needs of the insane.

## HYDRASTIS CANADENSIS IN UTERINE HÆMORRHAGE.

HYDRASTIS *Canadensis*, or Golden Seal, has been long used in this country as a pure bitter in atonic dyspepsia. The root of hydrastis contains berberin and hydrastin, both of which are believed to have a vaso-constrictive action on relaxed mucous membranes, thus ameliorating congestive states.

Professor Schatz, of Rostock, Germany, was the first to bring hydrastis prominently before the medical public as a uterine tonic. He contrasts it with ergot, which it resembles in its action, but he finds it efficient in cases of uterine hæmorrhage where ergot is powerless. In menorrhagia from whatever cause, in hæmorrhages due to metritis and endometritis, to myoma, to incomplete involution of the puerperal uterus, he has found hydrastis invaluable. Professor Schatz's mode of administration is to give the fluid extract in twenty-drop doses four times a day, and not only when the hæmorrhage continues, but also from one to two weeks prior to the time that the menstrual period sets in, especially in the congestive form.

Since the publication of the paper of Professor Schatz, Professor Slavatsky, of St. Petersburg, has made some interesting experiments with hydrastin, from which he has found that this alkaloid has an æbolic effect on pregnant animals (bitches and rab-

bits), and when given to parturient women, it expedites labor. He puts the maximum dose of hydrastis at one-half grain.

The latest contribution to the subject of the uses of hydrastis in uterine hæmorrhage is by Dr. R. W. Wilcox, in the *New York Medical Journal*, February 19, 1887. His conclusions are based on the observation of the effects of this drug in fifty cases. In three of uterine fibro-myomata, in which he gave hydrastis for metrorrhagia, the flow was speedily checked. Persistent use of hydrastis (for months) was followed by considerable reduction in the depth of the uterine cavity and in the volume of the uterus. Wilcox concludes that hydrastis arrests the bleeding from fibro-myomata by the production of anæmia of the uterine tissues, and he refers to the physiological experiments of Mays, a year ago,<sup>1</sup> which showed "that hydrastin in small doses increased blood pressure, while causing vaso-motor contraction, cardiac inhibition, and anæmia of the alimentary mucous membrane. Mays observed also, uterine contraction, even of the body and horns of the uterus." Fellner, moreover, in some experiments made in 1885, with fluid extract of hydrastis, noticed uterine contractions and anæmia of that organ.

In seven cases of hæmorrhagic endometritis, five being cases of endometritis fungosa, marked benefit was noted under the use of hydrastis. Dr. Wilcox remarks that "in endometritis fungosa, we have in hydrastis a sovereign remedy, even when curetting has failed to arrest the bleeding."

Sixteen cases of subinvolution of the uterus were treated satisfactorily with hydrastis. Five cases of climacteric hæmorrhage were also benefited by the same drug, and the same is said of nine cases of pelvic inflammation and three of congenital antelexion. So enthusiastic is Dr. Wilcox over this remedy, that he is disposed, we think, to underrate the value of local examinations and local medications, which he says, "are entirely unnecessary." He gives the fluid extract of hydrastis in twenty-drop doses three or four times daily in a wineglassful of water.

#### SMALL-POX AMONG RAG-SORTERS.

ABOUT the 18th of February last, three cases of small-pox appeared nearly simultaneously among the employes of the Parsons Paper Company, of Holyoke, Mass., no previous case having existed in the city for many months. Of these three persons one was a man who had never been vaccinated and who worked at the duster, dusting both foreign and domestic rags. This man had a severe form of the disease and died. He lived in a house at some distance from the one occupied by the other persons.

The other cases were in the persons of two girls of Irish nativity, aged respectively twenty-five and sixteen, both of whom were said to have been vaccinated

in infancy, but neither of whom presented typical vaccinal scars. The former had been revaccinated since working in the mill but without success. This one had worked as a rag-sorter for five or six years, the younger one only about eight months. They occupied the same bed in a boarding-house. The younger had been out from the mill on account of slight indisposition for a week before her seizure with small-pox.

The two girls worked on opposite sides of a rag-sorting room, the smaller of two with which the mill was supplied, accommodating thirty-five or forty girls. In this room no rags had for a long time been sorted except (1) new shoe-cuttings from eastern Massachusetts, which had, of course, not been through the duster and which were the scraps of new cotton cloth left from the linings of shoes; (2) foreign "number 1" linens, of two separate marks, the one (one-third of the total amount) being of German origin, and the other (two-thirds of the total amount) being Russian, but both sorts being shipped from Hamburg, the former imported through a Boston house and the latter through a New York firm. It is said that the exporter of the German rags had a quantity of this same mark of rags lying loose in his warehouse for a period of two years before they were baled up. They bore the certificate of the resident United States inspector to having been disinfected by the sulphur process. In passing to and from their work these girls, with all the other workers of that room, were obliged to go through the larger rag-sorting room of the mill in which domestic rags were sorted. In this latter room no cases of small-pox have occurred. The girls both had the disease in a light form and have nearly recovered.

This is the sum and substance of the whole matter as disclosed by an investigation on the part of the State Board of Health. Contagion altogether outside the paper-mill is not excluded, contagion from domestic rags is not excluded. The result of the inquiry is negative. Even the most eager proprietor of a patent disinfecting process would scarcely venture to find therein more than a mild presumptive conclusive proof, the ardent disinfecter should not fore-evidence against the foreign rags. Even were there get the difference in behavior between the virus of small-pox and that of cholera.

#### HOW MANY SUBSCRIBERS READ THE REPORTS OF THE MEDICAL SOCIETIES?

ONE of the newest comers in the field of medical journalism<sup>1</sup> announces that it will print no society reports. It makes the startling statement *based on the experience of the editors* (?) that these reports are not read once in a thousand times! [sic.]

Here is a problem worthy of the medical statistician. How many readers of medical periodicals *never* read the society reports? How many read them *only once* "in a thousand times?" How many *always* read

<sup>1</sup> Therapeutic Gazette, May, 1886, p. 289.

<sup>1</sup> Philadelphia Medical Register, Vol. I, No. 1.

these reports? How many prefer "a weekly *résumé* of all that is going on in the medical world," the society reports being left out?

As we do not believe that the editorial consciousness sums up all experience, we wait for more light.

Meanwhile we have done what we could to obtain it, consulted six representative men of the profession whom we know to be diligent readers of medical journals. All affirm themselves constant readers of the society reports, which they regard as indispensable portions of medical news, and believe the very brevity in which these reports are presented to be a merit. One of these gentlemen expressed the opinion that the larger and more elaborate articles in the medical journals were seldom read, while the society reports were at least always "skimmed over." Another thought that few cared for the *editorials*, (we record this as an impartial journalist), while everybody was interested in knowing what was said and done at the medical meetings.

#### MEDICAL NOTES.

— The Legislature of Maine has repealed the charter of the "Druidic University," on evidence presented of the fraudulent character of the institution. The Eclectic Medical College has also surrendered its charter, thereby escaping an official investigation which would probably have resulted in action similar to that taken in the case of the Druidic College.

— A Western contemporary tells a story illustrating the oft-repeated truth that the surgeon cannot afford to neglect applied mechanics and physics: A young lady had her finger caught in the valve of an air-gun. A physician being called, after careful consideration, decided that the only means of releasing the finger was to amputate it. This being done, the gunsmith arrived, and proceeded to release the amputated finger by boring a hole in the chamber of the gun.

— In regard to the overcrowding of the profession in the Australasian Colonies, the *Australasian Medical Gazette*, January 15th, says: "In New South Wales quacks are rampant, and can practise without the control of any law restricting their doings. A first-class man will, of course, succeed here after he has made a reputation, as he would do almost everywhere; but the prospect is not sufficiently good to justify us in refraining from advising unknown men against rashly rushing out here on mere chance. Appointments are not so easily obtained as formerly; and, for every vacancy, a perfect rush is made by numbers of eligible men — in one instance, lately, upwards of sixty making application.

#### NEW YORK.

— On March 2d, the sum of \$53,050, which was raised by the annual collection of the Hospital Saturday and Sunday Association this season, was distributed to the various hospitals belonging to the Association.

— The twelfth annual commencement of the American Veterinary College was held at Chickering Hall, on the evening of March 4th. The diplomas were presented by Prof. F. D. Weisse, and the prizes by Prof. C. A. Doremus. Frederick R. Coudert, Esq., made the address to the graduating class, which numbered forty-four.

— The twenty-eighth annual commencement of the Long Island College Hospital, was held at the Brooklyn Academy of Medicine, on the 1st of March; when degrees were conferred upon thirty graduates, by Dr. Joseph C. Hutchinson, who has been elected President of the Collegiate Department in place of the late Dr. Dudley. The seventh annual dinner of the Alumni Association of the college was held February 28th, and was attended by the Mayor of Brooklyn.

— A Kings County Association, similar to the New York County Medical Association, and in affiliation with the State Association, has been organized by the Fellows of the latter residing in Brooklyn, with the following officers for the first year: President, Dr. E. R. Squibb; Vice-President, Dr. Avery Segur; Recording Secretary, Dr. R. M. Wyckoff; Treasurer, Dr. J. R. Vanderveer. The new association is to meet once a month in Remsen Hall, and the social element will be made a special feature of its reunions.

#### Miscellany.

##### AUTOPSY OF PROFESSOR SCHROEDER.

THE autopsy of Schroeder, the details of which were announced by Virchow to the Berlin Medical Society, showed that the eminent gynecologist died of abscess of the cerebrum. This abscess was encysted; was situated at the posterior part of the foramen; impinged on the white substance of the occipital lobe, and extended into the right lateral ventricle, which cavity was also the seat of a fibrino-purulent inflammation. Schroeder had been suffering from a violent ophthalmia, from infection by a suppurating wound, but the cause of the cerebral abscess is not apparent.

Professor Schroeder was born September 11, 1838. He was Professor at Erlangen since 1868; his "Treatise on Obstetrics," which went through four editions in as many years, first appeared in 1870. He is best known in this country by this work, and his "Manual of Diseases of the Female Sexual Organs," which forms Volume X of "Ziemssen's Cyclopædia."

##### THE PAY OF MEDICAL OFFICERS IN THE ARMY AND NAVY.

THE *Medical News* gives the following facts regarding the compensation in these two branches of the public service. The pay of the Assistant Surgeon in the Navy, for the first five years after his appointment, is, per annum, when at sea, \$1,700; when on shore duty, \$1,400; when on leave, or waiting orders,

\$1,000. After five years' service, his pay becomes, at sea, \$1,900; on shore duty, \$1,600; and when waiting orders, \$1,200. There seems to be no good reason for the difference in pay for sea and shore duty.

The pay of the Assistant Surgeon in the Army, for the first five years after his appointment, is, per annum, \$1,600, and, after five years, \$2,200. For the first ten years of service, or thereabouts, the pay of the Army medical officer is somewhat greater than that of the Navy medical officer. But promotion is more rapid in the Navy than in the Army, owing to the fact that the Navy has more officers in the higher grades. Thus, of 180 medical officers in the Navy, there are 15 with the rank of Colonel, and 15 with rank of Lieutenant-Colonel; while, of 192 medical officers in the Army, there are 5 Colonels and 10 Lieutenant Colonels. The result of this is that while in the Army it requires about twenty years' service to reach the rank of Major and full Surgeon, in the Navy it requires a little less than fifteen years to attain this grade. Taking it altogether, there is very little difference in the pecuniary emoluments of the two services.

#### OLFACTORY ACUTENESS.

An interesting contribution was recently made by Messrs. Nicholls and Bailey to *Nature*, giving the results of experiments upon the relative acuteness of the sense of smell in individuals. A series of solutions of oil of cloves, nitrite of amyl, extract of garlic, bromine, and prussic acid were prepared by successive dilutions with water until the limit of perception was reached, and then the solutions were placed indiscriminately and submitted to a number of persons of both sexes to classify them properly by the sense of smell. The results showed that on the average the sense of smell was much more delicate in the males tested than in the females; but the degrees of keenness ranged widely as between individuals. Thus three male observers were able to detect one part of prussic acid in 2,000,000 parts of water, though its presence was not revealed by a chemical test; but others, of both sexes, could not detect prussic acid in solutions of almost overpowering strength. The following figures give the average limit of delicacy of perception: Cloves — Males, 1 in 88,128; females, 1 in 50,667. Nitrite of amyl — Males, 1 in 783,870; females, 1 in 311,330. Extract of garlic — Males, 1 in 57,927; females, 1 in 43,900. Bromine — Males, 1 in 49,254; females, 1 in 16,244. Prussic acid — Males, 1 in 112,000; females, 1 in 18,000. — *Medical Press and Circular*.

#### Correspondence.

##### CONTRACTED FINGERS.

BROOKLINE, March 1, 1887.

MR. EDITOR.—In connection with Dr. Homans' article on "Contracted Fingers," in the issue of the JOURNAL of February 24th, a case lately under my observation may be of interest in respect to its etiology. It is that of a tailor, who, when married, in 1853, placed a plain gold wedding ring on the little finger of his left hand. He was then of slight build but soon grew stouter and the ring, which fitted his finger easily before, became quite tight, although it caused him no inconvenience. About seven or eight

years ago he suddenly felt a flash, as he expressed it, like lightning running down his left arm, from the shoulder to the finger; this happened again in about a week, and he then had the ring cut off. From that time his finger began slowly contracting and in two years its tip had nearly touched the palm of his hand. It has been about stationary since then. The little finger is the only one at all contracted. He is sure that it was the tight ring, which he wore for a number of years, that caused the contraction. He still works at his trade with but little inconvenience from the trouble. Very truly yours,

BENJ. S. BLANCHARD, M.D.

##### THOMASVILLE, GEORGIA, AS A WINTER RESORT.

A VALUED contributor writes us from the Mitchell House, Thomasville, Georgia, under date of February, as follows:

I have written you, in former years of the wonders of this place, in the way of perfect drainage, entire salubrity and absence of any bad endemic influence. It is infinitely preferable to any place in Florida, since we have many pleasantly cool days all through the winter, and are free from the malarious misery of the St. John's Valley, for which a visitor is furnished with free tickets the whole winter through.

Another great advantage over the so-called "Land of Flowers" is the unlimited area over which one may ride, drive or walk. Last week, after a long, hard, drenching rain of five or six hours, the sun shone out brilliantly, about noon. Wearing our every-day thin walking shoes we went out for a long stroll. We came in with our feet as free from mud or wet as if we had walked on the *trottoir* of Beacon Street, in May.

To-day, in taking our long ante-meridian stroll, on the home-stretch I was obliged to take off my coat and walk in my shirt-sleeves. I did not take cold, for the song of the mocking-bird so soothed and satisfied the soul that a chill was an impossibility.

As for equestrian life, it is to be found in all perfection. The saddle-horses are of the best and are not dear to the rider. Within a circle, the radius of which is five miles having its centre in my *salon*, there are one hundred miles of excellent roads for driving. To the angler and the sportsman Thomas County is paradise. Within sight of my bedroom window I have made a bag of ten quails and eleven snipes. One can do it now, if permission be given by his Honor the Mayor, my great friend and crony, who lets me shoot anywhere within the city limits.

One more recommendation. An excellent doctor (Thomas S. Hopkins, graduate forty years ago of the University of Pennsylvania) is the *Æsculapius* of the place. He is one of those of our guild in *his partibus* who have kept up with medical progress.

Board, at this sumptuous hotel is \$4 per day, to transient people. The town is filled with good boarding-houses, the keepers of which ask from ten to fifteen dollars per week. A Pullman will soon bring people from Boston or New York to our station, without change, and for about \$30 per ticket.

I wish more northern doctors knew what I know from a series of years of this wonderful corner of the vineyard! I have just bought me a ranch of some 1,600 acres, on account of the excellent shooting and fishing obtainable on it. What would you Bostonians have said, had you seen us lying on my big wagon robe, *à fresco*, at noon, whilst taking our bit of luncheon, the while our horses and doggies were getting their second wind for the afternoon shoot?

On the bill of fare I enclose, the dishes were as good as those you and I used to get in Paris "in the days when we were young." It seems more like a miracle than an ordinary fact to find such an ideal hotel as this.

Therefore, when you get tired of snow and ice and han-

ners with the cold device, come to us and see what a wonderful country it is that we Americans possess. To me it is far preferable to California.

# THE SPINAL CORD, IN HEALTH AND DISEASE, AT THE REGION OF THE FOURTH AND FIFTH DORSAL VERTEBRÆ.

BELFAST, IRELAND, 5 College Sq., North,  
January 21, 1887.

MR. EDITOR.—When I published in the *Lancet* of July 12, 1884, an abstract of my views "On the spinal cord, in health and disease, at the region of the fourth and fifth dorsal vertebræ," and followed this paper by a relation of clinical results in accordance with its teaching, on the following December 6th, I felt assured that in America, where neurological science has attained to such a prominent position, my novel proposition would, sooner or later, attract the notice of thoughtful men, of journalists, and of physiologists, and I have not been disappointed.

Among others, the *New York Journal of Nervous and Mental Disease*, of January, 1885, and your *JOURNAL* of October 14, 1886, through its learned contributor, Dr. Morton Prince, have introduced the subject to their respective readers. With your permission I am desirous of dealing in your pages with the comments of the latter eminent physician; as to the style or manner of Dr. Prince's stricture I have nothing to complain. He appears to be a sincere searcher after physiological truth; when he could honestly agree with my teaching, he did so, very candidly; when he could not succeed to the same extent in evolving the latent phenomena of spinal hyperæsthesia, he did not suggest, that, therefore, they had no existence. I trust that I shall be able to convince him, that, although he could not always demonstrate the presence of spinal tenderness in the limited area referred to, yet, that in every case it was substantially there, and that if he pursue the subject in the same judicious manner in which he has begun, he will, day by day, be rewarded by an increasing percentage of positive results, till with me he shall attain the maximum of cent. per cent.

Applying myself, in the first instance, to the constant existence in the sound, equally with the unhealthy, of a sensitive region in the cord limited to the space covered by the spinous processes of the fourth and fifth dorsal vertebræ, and the doctor's inability to detect the phenomenon in every case, his failure was evidently due to defects, objective and subjective, in the mode of examination. Were the doctor, for the first time, presented with that little wooden cylinder invented by Lenæce, and told of its wondrous power, through mediate auscultation, of discovering and discriminating heart and lung diseases, he would not surely condemn the instrument as a plaything because it did not at once reveal to his unpractised ear the various *râles* and *bruits* with whose discovery it was associated. In like manner, although the subject of his recent experiments did not respond to the taps of his forefinger, as they most assuredly would have done to the knuckle of my middle finger, the fault did not lie in the test, but in the want of familiarity in its application.

In fact it frequently occurs, both in the delicate and the robust, that on the first trial the subject declares that he feels no difference whatever when percussed over the fourth or the remaining eleven dorsal vertebræ, and, were the experimenter satisfied with this assurance, all further inquiry would cease. Brown-Séquard<sup>1</sup> refers to this peculiarity, and says: "Its existence, however, might not be found out, if questions were merely asked, or a cursory examination were made, as the symptoms may be slight and localized in one vertebra, and the patient may not be aware of their presence." Further on, same page, he continues: "It is well, when we have to deal with hysterical or timid patients, to judge of the degree of tenderness more from the sudden and involuntary movement of the

spine, when we press on it, than from the patient's statements as regards the degree of local or referred pains felt. The amount of blushing of the face when a tender spine is pressed upon is also a means of appreciating the degree of tenderness, especially when the affected part is in the lower third of the cervical region, or the upper third of the dorsal region."

So much for subjective consciousness of hyperæsthetic phenomena. My mode of procedure, especially in healthy subjects, is as follows: having bared the back, from the nape of the neck to the waist, I request that the arms be folded across the chest so as to put the integuments covering the spinous processes upon the stretch; this is especially necessary in the case of fatty subjects. I then tap smartly, not heavily, with the knuckle of my middle finger over the spinous processes from the first cervical to the last dorsal; the vertebra prominens, though the least protected, never exhibits any signs of uneasiness; I expect, when arriving at the fourth and fifth dorsal, a response, and an involuntary twitching of the integument, but, if the patient, on passing over the remaining dorsals, declares that he feels no inordinate pain over any of the twelve, I say, *I know better than you*, I shall again go over the back, pay more attention, and when I reach a tender point speak at once; when I, for the second time arrive, at the sensitive fourth and fifth, he at once complains of pain, "Oh, yes, that will do; I cannot bear that"; however, to make matters more apparent, I generally percuss the spine again in both regions; when I am met with a protest against further procedure, as the pain at the spot referred to becomes too much for his patience. He likens the pain often to that of neuralgia, and I have been assured in several instances that the uneasiness has continued for one or two days after the date of examination.

Occasionally, as a preliminary, I pass a finger on either side of the spinous processes of the dorsal vertebræ, leaving a red streak on each side, just over the transverse processes or the neurotic arches of the vertebræ; after this procedure the response over the region in question is more ready and complete, and I prefer the knuckle of the middle finger in percussing, as the impact there is more equable and sure.

It was not possible in my original communication to the *Lancet* to enter into these details; my idea was to put forward the leading principles, leaving circumstantial directions for future occasions.

While Dr. Prince's comments on the therapeutical value of my treatment were on the whole favorable, my respected critic was, unintentionally I am sure, unjust to me; for, while giving the remedy credit for some remarkable cures in various cases of neurotic disorder, he enumerates others of that class in which it failed to cure—cases outside the list which I have published and in which I never recommend its use, and although I added the words, "and other neuroses," I did not mean to attest its efficacy in *all* other neuroses, especially those of an organic nature; for instance, neurasthenia, in which I had especially recommended deviations from the region of the medulla oblongata in the neck, or in any paralysis except facial, in which it was very successful; I certainly never suggested its use in tabes, progressive muscular atrophy, rheumatism or tobacco neurosis. In chorea I do not always succeed by counter-irritation over the dorsal spines, and I declared my failure in one of the cases published, having to supplement the treatment by dry cupping. It is evident that failures in these special disorders does not affect the integrity of my general statements.

And although Dr. Prince was more successful in discovering the special dorsal tenderness in cases of disease, yet, he affirms, that he also found the symptoms in other vertebræ in the absence of pain in the fourth and fifth; these were possibly cases of reflected or transmitted pains from congestive or follicular disease of the stomach or intestines or other abdominal disease; as pathologists recognize that the healthy condition of the spinal nerves is often depen-

<sup>1</sup> Spinal Irritation, Quain's Dictionary, page 1506.

<sup>2</sup> The Medulla Oblongata in its Relations with Sexual Disease. Practitioner, July, 1884.

dent on the integrity of the viscera supplied by them. General tenderness of the spine was noted, he says, in four cases. These were most likely cases of general rachialgia, in such cases pain produced by pressure on one spinous process extends, according to Brown-Sequard, to the whole vertebral column.<sup>2</sup>

Finally, Dr. Prince has recorded a number of "strikingly successful cases" due to my plan of treatment, and referred to others such as the "Vomiting of Pregnancy," in which it was "eminently successful;" he has also given the particulars of others of an incurable nature, in which great relief from pain was experienced; the results of his experiments, he says, "seem to aid in giving the proper value

<sup>2</sup> Article on Spinal Irritation, as quoted above, Quain's Dictionary of Medicine.

to spinal tenderness as a symptom, as well as to a therapeutic procedure which, in suitable cases, must prove of unquestionable utility;" and he concludes by stating "decided and beneficial effects may often be obtained by blistering over the fourth and fifth dorsal vertebra in various neuroses."

I have not any doubt that Dr. Prince's commentary read in the light of this explanation, will have the effect of engaging the attention of many of my transatlantic brethren, and of encouraging further experiment on the lines laid down in my original monograph; at any rate I must feel indebted to Dr. Prince for his well-balanced and highly judicial pronouncement on my little brochure.

ALEXANDER HARRIN, M.D., F.R.C.S., England,  
Consulting Physician Mater Infirmorum Hospital, Belfast.

# REPORTED MORTALITY FOR THE WEEK ENDING FEBRUARY 26, 1887.

Deaths reported 2,459: under five years of age 935; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas and fevers) 328, acute lung diseases 405, consumption 358, diphtheria and croup 139, measles 65, typhoid fever 31, scarlet fever 20, malarial fevers 20, diarrheal diseases 18, cerebro-spinal meningitis 13, whooping-cough six, erysipelas four, small-pox three, puerperal fever one. From scarlet fever, New York 14, Brooklyn seven, Philadelphia six, Pittsburgh two, Baltimore, Cleveland, and Fall River one each. From malarial fever, New York nine, New Orleans six, District of Columbia two, Philadelphia, Brooklyn and Richmond one each. From diarrheal diseases, New York five, New Orleans four, Philadelphia, Brooklyn and Cleveland two each, District of Columbia, Pittsfield and Providence, one each. From cerebro-spinal meningitis, New York, Philadelphia, Pittsburgh and Haverhill two each, Cleveland, Providence, New Haven, Lowell and Fitchburg one each. From whooping-cough, Brooklyn two, New York, Baltimore, Richmond, and Lawrence one each. From erysipelas, Philadelphia two, Brooklyn and Cleveland one each. From small-pox, New York two, Brooklyn one. From puerperal fever Baltimore one.

Cases reported in Boston: measles 62, scarlet fever 25, diphtheria 23, and typhoid fever 10. Twenty-three cases of measles were reported in Newport, R. I., for the month of February but no deaths.

In the 22 cities and greater towns of Massachusetts, with a population of 1,017,956 (population of the State 1,941,465) the total death-rate for the week was 20.68 against 20.52 and 20.89 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,245,069, for the week ending February 12th, the death-rate was 19.5. Deaths reported 3,453: infants under one year of age 811; acute diseases of the respiratory organs (London), 373; whooping-cough 95, measles 77, scarlet fever 61, diphtheria 43, diarrhoea 32, fever 31.

The death-rates ranged from 14.9 in Nottingham to 30.1 in Huddersfield; Birkenhead 18.7; Birmingham 18.9; Derby 16.1; Halifax 18.4; Hull 20.9; Leeds 16.9; Leicester 15.3; Liverpool 26.9; London 17.6; Manchester 28.8; Newcastle-on-Tyne 22.6; Portsmouth 21.6; Sheffield 20.5.

In Edinburgh 21.6; Glasgow 24.8; Dublin 27.3.

The meteorological record for the week ending February 26, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending Saturday, Feb. 26, 1887.	Barom- eter.	Thermometer.				Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather. <sup>1</sup>			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM FEBRUARY 26, 1887, TO MARCH 4, 1887.

GREENLEAF, CHAS. R., major and surgeon. Ordered for duty in the office of the Surgeon General of the Army. S. O. 41, A. G. O., February 18, 1887.

HUNTINGTON, D. L., major and surgeon. Will be relieved from duty in the office of the Surgeon General, to take effect March 1, 1887. S. O. 41, A. G. O., February 18, 1887.

HUNTINGTON, DAVID L., major and surgeon. Ordered for duty at San Diego Barracks, Cal., and granted leave of absence for one month from March 1, 1887. S. O. 45, A. G. O., February 25, 1887.

WHITE, ROBERT H., captain and assistant surgeon. On being relieved by Major Huntington, to proceed to Angel Island, Cal., and report to commanding officer for duty at that post. S. O. 45, A. G. O., February 25, 1887.

TESSON, LOUIS S., captain and assistant surgeon. Ordered for duty as attending surgeon at headquarters, Division of the Missouri and Examiner of Recruits at Chicago, Ill. S. O. 44, A. G. O., February 24, 1887.

GRAY, WM. W., captain and assistant surgeon. Leave of absence for seven days is extended twenty-three days. S. G. 13, Department of Dakota, February 21, 1887.

MASON, CHAS. F., first lieutenant and assistant surgeon. Resignation accepted by the President, to take effect, March 23, 1887. S. O. 44, A. G. O., February 24, 1887.

#### OBITUARY.

##### LUTHER PARKS, M.D.

Luther Parks, A.M., M.D., whose death was previously announced, was born in Boston, November 4, 1825, and graduated at Harvard College in 1843, taking high rank in a class which included many men who have become distinguished.

He took his degree of M.D. in 1847, and in the same year went to Ireland as surgeon of the United States Sloop of War "Jamestown," which was sent, loaded with provisions, to relieve the starving Irish people. He was there made a Fellow of the Royal College of Surgeons of Ireland. After his return he married Miss Julia Dale, and established himself at the south end of Boston. In his active practice there of eleven years, during a portion of which he served as one of the District Physicians of the Boston Dispensary, he was notable for conscientious fidelity and kindness toward his patients, and for his skill as an obstetrician, which he took pains to perfect, by practical work at the Rotunda Lying-in Hospital at Dublin, during a second visit to Europe in 1852. After the death of Mrs. Parks in 1859, he again went abroad, everywhere interesting himself in what was being done in the profession.

Dr. Parks married in 1861 Miss Catharine Burroughs, and, at the request of his father who was advancing in years, he removed to Chestnut Street and retired from active practice. During the late war, at the solicitation of Governor Andrew, who was his personal friend, he went to the peninsula of Yorktown as a volunteer surgeon.

After his father's death, Dr. Parks again went in 1872 to Europe, where he continued to reside until his death, at Pau, November 19, 1886, at the age of sixty-three. His widow, his son, Dr. Edward L. Parks, of Boston, and two married daughters survive him.

Dr. Parks was for some years one of the physicians of the

Boston Lying-in Hospital, and was associated with Dr. S. L. Abbot, as editor of the *Medical and Surgical Journal*. At the Annual Dinner of the Massachusetts Medical Society in 1871 he presided as Anniversary Chairman. As Chairman of a Committee of that Society he carefully investigated and reported upon an epidemic of cerebro-spinal meningitis in Massachusetts. Although absent, and retired from practice, he retained to the end of his life his Fellowship in the Society, and his interest in its work for the promotion of medical science. As an exemplar of scrupulous fidelity, energy, and courage in the discharge of duty as well as for his loyalty and courtesy, Dr. Parks will not be forgotten by his professional brethren.

##### DR. LEWIS FISHER

Dr. Lewis Fisher, who practised successfully in New York for many years, died February 28th, at Jacksonville, Fla. He was born in 1829, in Mobile, Ala., whither his family had gone from Philadelphia. He was graduated from the Medical Department of the University of the City of New York in 1861, and soon afterward entered the medical service of the army. For a considerable portion of the late war he was in charge of the hospital at Chester, Pa., and at the close of the war he settled in Morristown, New Jersey, for a time. While living in New York he spent a number of summers at New London, Ct., where he had a lucrative practice. For some time previous to his death he had been in failing health, and it was on account of this that he went to Florida. His brother is a practising physician in Hoboken.

##### SOCIETY NOTICE.

SUFFOLK DISTRICT MEDICAL SOCIETY. OBSTETRIC AND GYNÆCOLOGICAL SECTION.—There will be a meeting of this Section at the large Medical Library Room, 19 Boylston Place, on Wednesday evening, March 16th, at eight o'clock. Communications: Dr. John Homans, 2d, "Supplementary Ovaries." Dr. W. H. Fales will exhibit a specimen and make some remarks upon a very interesting case of Lithopædion, which the patient carried for thirty years, finally dying of cancer. Refreshments after the meeting.

JAMES R. CHADWICK, M.D., Chairman.  
ROBERT B. DIXON, M.D., Secretary.

##### BOOKS AND PAMPHLETS RECEIVED.

Annual Report of the Board of Managers of the New York State Reformatory at Elmira, for the Year ending September 30, 1886. 1887.

Massage as a Mode of Treatment. By William Murrell, M.D., F.R.C.P. Second Edition. Philadelphia: P. Blakiston, Son & Co. 1887.

The Antiseptic Treatment of Summer Diarrhoea. By L. Emmet Holt, A.M., M.D., Attending Physician to the New York Infant Asylum. 1887. (Reprint.)

Two Unique Cases of Insanity: possibly Epileptic. By Theo. W. Fisher, M.D., Superintendent of the Boston Lunatic Hospital, Boston, Mass. 1887. (Reprint.)

Handbook of Materia Medica, Pharmacy and Therapeutics, including the Physiological Action of Drugs, the Special Therapeutics of Disease, Official and Extemporaneous Pharmacy and Minute Directions for Prescription Writing. By Samuel O. L. Potter, M.A., M.D., Professor of the Theory and Practice of Medicine in the Cooper Medical College of San Francisco, etc. Philadelphia: P. Blakiston, Son & Co. 1887.

## NOTES ON THE DIGESTION OF "LIVING" TISSUES.

BY JOSEPH W. WARREN, M.D.,

Assistant in Physiology in the Medical School of Harvard University.

In a recent number of the *Biologisches Centralblatt*, Frenzel<sup>1</sup> has again called attention to this enigma of the digestive process, which, ever since John Hunter's day, has awakened much interesting and ingenious speculation, but which is hardly nearer a solution now than then. The question is: Why do organisms which manifest such power of digesting and assimilating the material they require, leave quite intact those organs or tissues where these processes go on so actively? Why does the stomach digest various albuminous substances so readily, and yet fail to attack its own walls, containing substantially the same material? Why do the intestines, with their much more varied power of digestive action, remain undisturbed and uninjured by this activity? Why does the pancreas secrete at least three vigorous digestive ferments, and yet work on unaffected by each and all of them? The same question may be urged concerning the various glands of many lower organisms which have a well-defined digestive tract; and the enigma only grows in difficulty and interest as we consider those forms of life where such a differentiation of organs does not appear to be present, and where processes at least analogous to the digestion of higher animals are carried on.

This immunity, in its completeness, is found only so long as the organism is alive. When death has occurred, a certain amount of post-mortal "self-digestion" is observable. The human stomach, for example, is not infrequently found with its walls so much softened and changed, that such a proteolytic action of its own secretions is supposed to have taken place. It has but rarely been observed that such changes are brought about before death. One of the few apparently authentic cases of ante-mortant self-digestion of the living human stomach was reported, a number of years ago, by Mayer;<sup>2</sup> and is given in detail, by Leube, in "Ziemssen's Cyclopadia."<sup>3</sup> It has been considered probable that, in ulcerations of the stomach, as well as in the course of cancerous changes of that organ, a certain amount of localized digestion of the gastric walls occurs, and this view has much in its favor.

Frenzel points out that a similar post-mortant transformation is observable in the entire animal kingdom. Certain sections of the intestines of insects are found thus self-digested; and the like change may be noticed in ferment-producing glands (the so-called "liver") of crustaceans and mollusks. He also considers that the rapid disintegration of many amebæ and infusoria is due to self-digestion by the ferments they produce while living. Ordinarily these rapid changes are attributed to the activity of the bacteria of putrefaction; but Frenzel reports an observation which seems to lessen the necessity of such an assumption, or, at least, suggest caution in its universal application. He studied a worm which lives in strong vinegar (*anguilla aceti*), where, as he says, he could find no microbes. This worm, after death, showed a rapid dis-

solution of its tissues; and Frenzel thinks that the secretions of its digestive organs must have played an important part in the process. It should not be forgotten, in this connection, that, so far as I know, it has not been demonstrated that these post-mortant changes are true digestions, and not merely transformations into soluble bodies, without the formation of peptones. This distinction, as I think we shall see, is not unimportant.

The explanations that have been given concerning the protection which living tissues appear to possess have varied in an entertaining and instructive manner. It would take too much space to point out all the different phases through which the discussion has passed; nor would it be very profitable to examine all the theories proposed concerning the conditions which favor the post-mortant softening of the stomach itself. The literature may be found in sufficient fulness in Leube's article, already alluded to, and in Wiederhofer's chapter on "Gastromalacia."<sup>4</sup> It will be enough for my present purpose to indicate the general principles which have been adopted, at various times, as the basis for an explanation.

It has been urged that the stomach preserves its integrity, first, on account of its life — by some "vitality"; or, on account of the protection afforded by its epithelium; or, again, because so much mucus is present as to enwrap the food, or cover the surface of the organ; or, finally, because the acid is neutralized by the alkaline blood, the exceeding vascularity of the stomach in active digestion rendering the acid harmless so soon as it reaches the tissues of the gastric wall. Each of these explanations, alone or in various combinations, has found its defenders; and yet no one of them, nor all of them together, can be considered satisfactory.

The supposititious protection afforded by the mucus<sup>5</sup> has the least claim upon our attention. This, if it worked by any alkalinity it possessed, could only hinder the proteolytic action by weakening the acid, whose presence is indispensable. If the protection be sought in the coating which is given to the stomach or to its contents, the explanation must at once appear to us to be unreasonable. How could any such coating be assumed to be permeable for acid and pepsine in one direction (that is, towards the mass to be digested), and to permit the passage of digested or dissolved material in the opposite direction (towards the gastric walls) and yet not allow the acid-pepsine mixture to pass with equal freedom.

Should we confine this explanation to the small intestine, with its alkaline digestion, as Claude Bernard seems to have done, a still further and more weighty objection may be found in the fact noted by Frenzel, that insects have no such layer of mucus in their intestinal tract, and yet no self-digestion occurs there during life.

The protection attributed to the epithelium, whether it be thought to lie in its own resistance to digestive changes, or in its rapid renewal, would appear also to be insufficient. It has been found that the epithelium may be quite extensively injured or removed,<sup>6</sup> and no digestion of the underlying tissue takes place. The

<sup>6</sup> Vol. VII, p. 261, of the *American Edition*.

reports of cases where sounds and stomach-pumps have produced lesions of the epithelium, appear to be confirmatory of the view that the protection of the stomach is not to be sought in this coating, or, at least, not alone therein.

The alkalinity of the blood and the lymph, as a possible defence against the attack of the gastric juices, would, at the first glance, appear to be much more acceptable. The localized self-digestion of ulcerations, or in cancer, might be attributed to altered blood-flow, and consequent lessening of alkalinity. In the marked case of gastromalacia given by Leube and Mayer, and already quoted above, the individual had extensive cicatricial contractions at the pylorus, as well as at the cardia; and these would probably materially alter the blood-supply.

In this connection, however, we may not pass over in silence an observation made, several years ago, by Edinger.<sup>7</sup> He injected a solution of alizarin into the bloodvessels, and inferred, from the color-changes, that the mucous membrane of the stomach has an acid reaction throughout a considerable portion of its substance when active digestion is going on. Unfortunately, his method is not delicate enough to permit a microscopical examination of the tissues.

Even if we accept fully the view that the alkalinity and vascularity of the gastric walls preserve them from digestive destruction, we advance but a little towards a solution of our larger problem. In the small intestines we find a no less active digestive process, and a much more varied one, which is carried on in an alkaline menstruum. If the alkaline blood protect the stomach, what is the power which guards the walls of the smaller intestines?

The oldest explanation is that commonly attributed to John Hunter. This finds the immunity of the digestive apparatus in its "life"—in its vitality. Modern biology cares so little for any "vital principle," that such a view seems almost absurd, since it merely answers one question by putting another—a method not quite out of fashion. Could we turn backward mentally, and think as did the strong men of old, as readily as we may masquerade in their clothes we should doubtless perceive that in this view John Hunter was fully abreast of his time. We might realize that we are not any too near an answer of our enigma nowadays, although we have turned the question completely round.

It is, perhaps, not without interest to read what Hunter wrote on this point. The original paper, "On the Stomach itself being Digested after Death," was presented to the Royal Society, and read June 18, 1772. It was printed in the sixty-second volume of the "Philosophical Transactions," and reprinted, with slight changes, as an appendix to "Some Observations on Digestion." The paragraphs which state the doctrine are as follows:<sup>8</sup>

"An animal substance, when joined with the living principle, cannot undergo any change in its properties but as an animal; this principle always acting and preserving the substance possessed of it from dissolution, and from being changed according to the natural changes which other substances undergo.

"There are a great many powers in nature which

the living principle does not enable the animal matter, with which it is combined, to resist, viz., the mechanical and most of the strongest chymical solvents. It renders it, however, capable of resisting the powers of fermentation, digestion (and perhaps several others), which are well known to act on this same matter, when deprived of the living principle, and entirely to decompose it." . . .

"Animals, or parts of animals, possessed of the living principle, when taken into the stomach, are not in the least affected by the powers of that viscus so long as the animal principle remains; hence it is that we find animals of various kinds living in the stomach, or even hatched and bred there: yet the moment that any of those lose the living principle, they become subject to the digestive powers of the stomach. If it were possible for a man's hand, for example, to be introduced into the stomach of a living animal, and kept there for some considerable time, it would be found that the dissolvent powers of the stomach could have no effect upon it; but if the same hand were separated from the body, and introduced into the same stomach, we should then find that the stomach could immediately act upon it.

"Indeed, if the first were not the case, the stomach itself ought to have been made of indigestible materials; for were not the living principle capable of preserving animal substances from being acted upon by the process of digestion, the stomach itself would be digested.

"We find, on the contrary, that the stomach, which at one instant, that is, while possessed of the living principle, was capable of resisting the digestive powers which it contained, the next moment, viz., when deprived of the living principle, is itself capable of being digested, not only by the digestive powers of other stomachs, but even by the remains of that power which itself had of digesting other things."

A similar statement, but much more picturesquely put, may be found among his posthumous papers. I quote from page 146, Vol. I, in the edition prepared by Owen.<sup>9</sup>

"The [power of the] containing [organ] may, and does depend on the disposition of the body and mind, not so much on the constitution or strength of the body; for many weak constitutions have vast power of digestion, and others the reverse. Its effects are immediate on dead substances; almost as quick as the effects of an acid on an alkali. Its power depends upon life; for as soon as life is gone, even in the most healthy, this power is lost, excepting what may be going on [at the time of death], which continues for a little time. It depends on a living principle in itself; but that which is to be digested must be dead, or have lost this living principle, or it cannot be dissolved. . . . If it was possible for an animal to live in the stomach of another animal, supposing digestion not to be going on in that stomach, it would then live while digestion was going on; for that animal would not be in the least dissolved, because the living principle in the animal would prevent or counteract the digestive quality of the stomach. If this was not the case then we might readily suppose that even though the animal life was not immediately affected by the digestive power, yet at last it might be destroyed by the external and extreme parts of the animal being

<sup>8</sup> I quote from page 151 of the "Observations on Certain Parts of the Animal Economy," by John Hunter. London, 1786.

<sup>9</sup> Essays and Observations on Natural History, Anatomy, Physiology, etc. 2 vols. London 1861.

digested, and so the animal be obliged to die, like a person with a mortification. But that a living animal will not be so dissolved is every day proved by worms, maggots or flies, living in the stomachs of many animals; and if it was a power that could act upon a part that had the living principle, as well as an acid can, then the stomach itself would certainly be dissolved. If one could conceive a man to put his hand into the stomach of a lion, and hold it there without hindering the digestive powers, the hand would not in the least be digested; and if the hand of a dead man was put in at the same time, whether separated or not from the body, that hand would be digested while the other would not."

A rather different but no less entertaining view as to the importance of the vital principle in the digestive act, may be read in the note below, although the point before us is not directly involved.<sup>10</sup>

The following extracts from Saumarez' "New System of Physiology," published at London, 1798, also illustrate the point of view taken by many at that time.

Vol. I, p. 15. "It is to the power by the energy of which every living system is protected and preserved from decomposition and decay, and by which the different substances it receives are assimilated and changed, that I attach the idea of Life."

Again, on p. 330, of Vol. I, we read: "And finally that the gastric juice possesses, the power not only of killing living, but of reanimating dead matter, was proved by some experiments made, I believe, by Mr. Hunter and Spallanzani. They thrust pieces of putrid flesh, tied by a string, into the stomach of some dogs; and after leaving it some time in that organ, they withdrew the meat; and found upon examination, that from being offensive it had become sweet, from being putrid it was fresh again. It is not, therefore, sufficient for the food, by the organs of sense to have been selected, by the teeth to have been committed, by the mouth to have been masticated, by the saliva to have been blunted and banded: it is by the active energy of the stomach alone, and the fluid it secretes, that it becomes digested and assimilated, that solid food is reduced to a fluid state, that it becomes killed as it were, and loses its old life, and then is animated anew, receiving from the living power of the gastric, the participation of life from the system to which it is applied." He adds in a foot-note: "That the food we receive must be killed by the stomach before it is vivified afresh is evident, from hence: If it retained its own living power in an eminent degree, it is possible to conceive that it might inoculate with the stomach, instead of being digested by it; and if it retained its living power without inoculating, the nature of that food would be always apparent: we should participate of the quality of the beasts on which we feed, and of the vegetables also." I purposely refrain from extending these quotations by referring to the part which a vital principle, under various names, was playing at this time in the views of the best thinkers on the Continent.

<sup>10</sup> See Fordyce: A treatise on the digestion of food. London, 1791. Page 176. "But in the same manner the action of the powers of the stomach, and other organs of digestion, upon the food, is necessary for those powers which occasion its decomposition and recombination to act, so that, although they are always present in the substances capable of being converted into chyle, yet nevertheless they are not exerted unless they are influenced by the action, or circumstances which they meet with in the organs of digestion of a living animal; so that no chyle ever has been, and most probably never can be produced, excepting in the organs of digestion of a living animal."

It must not be supposed that the unsatisfactoriness of these arguments has only been recently recognized. I will spare the reader quotations which would demonstrate that quite early in the present century the "vital principle" was considered a vague and insufficient explanation of the difficulty. It was not, however, until the second half of the century had begun that an experimental refutation of John Hunter's theory was made — at least so far as it concerns the question now under discussion.

It is only about thirty years ago, the reader will remember, that Claude Bernard<sup>11</sup> found that gastric juice, injected under the skin, digested the subcutaneous tissues. He saw further, that the legs of a living frog inserted in the gastric fistula of a dog, were digested off to a great extent in about three-quarters of an hour, the rest of the frog remaining alive. A similar experiment was made with snakes. These observations were confirmed by Pavy,<sup>12</sup> Harley,<sup>13</sup> and others; they were extended by the partial digestion of the ear of a living rabbit. It thus became evident that the "life" of the animal could have but little to do with the protection of its digestive canal from proteolytic changes. The external and extreme parts did undergo digestion and the animal was not obliged to die, the very thing Hunter said could not happen.

Frenzel suggests that these experiments really only showed a partial solution of the "living tissues" and did not absolutely demonstrate their digestion — that is, their peptonization. He accordingly tried an artificial digestion of "living" tissues and arrived at interesting results. Several years ago I made a number of similar experiments and reached generally the same conclusions as those now printed by Frenzel. I reported my work at a meeting of the Boston Society of the Medical Sciences in the spring of 1883, but published nothing. It seems desirable to note them now as confirming the work of Frenzel and somewhat extending it, and I do so without intending to claim any priority for the method or the results.

Frenzel's experiments were made by fastening a frog on a forked board so that each leg hung in a vessel which contained hydrochloric acid (0.2 per cent.) or acid and pepsine. In the latter case marked changes were soon observable. The skin freed itself in patches and the flesh gradually disappeared especially on the parts where the epidermis was removed. In such places the bone was fully exposed in about an hour and a half. The bloodvessels were also affected; the walls burst, the blood exuded and coagulated, and the coagula were finally dissolved. On examination the liquid in which such a leg hung was found to contain peptone — there had been a genuine digestion. The other leg, hanging in acid alone, is said to have shown no special change save that the outer layers of

<sup>11</sup> In Bostock's Chapter on Digestion, in Todd's Cyclopaedia of Anatomy and Physiology, 1836-39, Vol. II, p. 23, he will find: "With respect, therefore, to the hypothesis of a vital principle, as maintained by Fordyce and many of the modern physiologists, we should say that it is rather a verbal than a real explanation of the phenomena, and that it rather evades the objections than answers them." See also: An Elementary System of Physiology. By John Bostock, Vol. II, (Boston reprint, 1826), p. 409.

<sup>12</sup> Claude Bernard: Leçons de physiologie expérimentale. Paris, 1854-56, Vol. II; Cours du semestre d'été, 1855, pp. 406-9.

<sup>13</sup> An account of Pavy's experiment with the ear of a rabbit, as well as his views concerning the protection afforded by mucus or epithelium, and the importance of the alkalinity of the gastric walls may be found in his "Treatise on the Function of Digestion," London, 1867, p. 74. The reader may also consult Pavy's paper: "On the Immunity enjoyed by the Stomach from being digested by its own Secretion during Life," in the Transactions of the Royal Society for 1863.

<sup>14</sup> Harley, loc. cit., p. 311.

the epidermis were slightly swollen. Where the epidermis had been removed a swelling and softening of the muscles was not observed — nor could such a leg be afterwards digested by pepsin in a neutral solution as would be expected had the muscles imbibed the acid. It should be added that the experiment was carried on at a temperature of 38° C. Frenzel does not say positively that such frogs remained alive, but it is to be inferred from the tone of his article that they did. He also reports that merely moistening an exposed muscle "at a suitable temperature" suffices to bring about an evident digestion. The number of experiments is not given.

My own observations were made on a large number of frogs; altogether about fifty of them participated in perhaps twenty experiments, but some died too early to make their share complete and useful. A detailed account of the methods employed and of the changes perceived may be omitted now, and I will generalize them as much as possible. Originally I only intended to modify Bernard's method for lecture purposes, and the lower legs of the frog hung in test tubes which stood in the water bath whose temperature was fairly constant (38° C). I was thus able to demonstrate that the lower legs could be much softened (or even drop off) and the rest of the frog remain alive — that is to say, the heart was still beating and the muscles of the upper leg responded perfectly to electrical or mechanical stimulation of the nerves. My occupations at the time unfortunately obliged me to leave the experiment unwatched over night. The results which this long exposure to acid alone produced differ from those of Frenzel in that the muscles were often much softened and even dissolved, but this effect was usually not so intense nor so extensive as where the leg was exposed to acid and pepsine. When, however, such solutions were compared, that produced by the aid of pepsine acquired a rose color with soda and cupric sulphate which only gave a purple color where acid alone had been active (Biuret reaction). In other words only the pepsine solution appeared to have really peptonized the muscle. Early in this work it occurred to me that the exposure to so high a temperature could not be a matter of indifference to the tissues. The frog is accustomed ordinarily to surroundings where the thermometer stands hardly ever higher than 15–18° C., and to remove him (or only his legs) suddenly and permanently to a climate where the mercury is always at 38° C., means a change such as would cause us much concern were we to make it ante mortem.<sup>12</sup> I accordingly repeated the experiments at room temperature with substantially the same results. Later, further modifications were introduced to lessen the possibility of disturbing the blood flow and the nutrition of the muscles by the hooks and bands which were needed to support the frog comfortably. Cutting the medulla oblongata as well as section of the sciatic plexus was tried, but the outcome of the experiment was the same and in general accord with Frenzel. I may add that control experiments were always carried on at the same time. Finally I followed a suggestion of Dr. H. P. Bowditch and curarized the animals, which enabled me to place the lower legs in little troughs containing the

digesting solution. In this way it was chiefly the gastrocnemius muscle which was exposed to the liquid, and this was favored by slitting the skin. By this means I was able to reach some very interesting results. It proved to be possible to digest (or at least make translucent and soft) a good portion of the exposed gastrocnemius, while all the rest of the same muscle was uninjured. That is, the undigested portion was firm and red as in health, and still manifested that perfect irritability which belongs to a sound muscle. It is hardly necessary to add that the other muscles of the leg, the heart, in short, all the rest of the frog remained fully alive. This took place too, it must be remembered, at a temperature in no way unfavorable to the animal's existence or comfort. A more instructive form of the digestion of "living" tissues cannot easily be found. On varying the strength of the acid it was seen that solutions ranging from 0.3 per cent. to 0.05 per cent. were positive in their results. No decided effect, however, was produced by a mixture of pepsine with 0.015 per cent. HCl. which was competent to digest boiled fibrin. It thus appears probable that a local digestion of a living muscle may be produced by pepsine and an acid of such strength that the entire amount of acid employed is less than that which the blood might be expected to neutralize. While I cannot maintain that my experiments were sufficiently numerous to settle this point, especially as I did not have this particular question in mind at that time, the notes made as the experiments progressed suggest a conclusion of this character. I purpose examining this point more exactly when I can find time for such work.

I also tried to attack the living muscles in an alkaline menstruum by means of such pancreatic extracts as we then had in the laboratory. The results were either negative or inconclusive, but the ferments at my disposal were not as good as we now have, and I consider this question open for further investigation.

Finally, then, we must admit that we are still far from a satisfactory explanation of the immunity of the various digestive organs with reference to their own ferments while "alive" and the lack of such protection when "dead." It might be suggested that many or all of the ferments come from their glands in a partially inactive condition (in form of a zymogen, as pepsinogen, trypsinogen and so on), but this consideration would have value only for the glands, and is useless for the stomach and intestine. Frenzel suggests, as Krukenberg<sup>13</sup> had already recently done, that the comparative physiology of digestion may be expected to solve our problem. Possibly the solution will prove to be less simple than we expect, and by showing us how exceedingly varied in principle the processes are which we have been accustomed to lump together under a single name as "digestion," also demonstrate that the safety of the "living" structures immediately involved is due to equally varied causes. Of course no one supposes that the tissues actually remain "alive" when the digestion begins. That part which is to be dissolved "dies" either before or during the digestion, but the direct cause which changes the living complex albumin molecule with its vigorous resistance to dissolution into some feebler form making it the victim of any enzyme which may happen to meet it, no man knows with certainty or completeness.

<sup>12</sup> This objection does not seem to have occurred to Frenzel. Pavy, however, may have had it in mind when alluding (loc. cit. p. 74) to "the more powerfully acting stomach of a warm-blooded animal like the dog," as the weak point in Bernard's experiment with "a cold-blooded reptilian animal."

## THE USE OF STROPHANTHUS HISPIDUS IN HEART DISEASE.

BY VINCENT Y. BOWDITCH, M.D.

A LITTLE more than a year ago, Professor Fraser, of Edinburgh, published the results of fifteen years' experience with a drug, till then, all but unknown to the medical profession. The feeling of respect due to such an accurate observer and careful experimenter as Fraser; the experience of several of our New York associates, as well as the comparatively recent facts brought to my notice in our own community, are the reasons of my calling your attention, this evening, to the use of strophanthus in diseases of the heart.

In the *British Medical Journal* of November 14, 1885, one may find the full account of Fraser's experiments; and I will, therefore, only call your attention to a few of the most important characteristics of the drug, hoping thus to induce you to give it a careful trial in your own practice, if you have not already done so.

The plant is indigenous to Africa, and is used by the natives as a poison for arrow-heads. It is of the digitalis group, and has a distinct action upon striped muscular fibre, and also upon the heart; and, in poisonous doses, causes greatly increased and almost continuous cardiac systole, with consequent paralysis of the heart and early cadaveric rigidity.

By a series of experiments patiently carried out over a number of years, both clinically and in the laboratory, Fraser has arrived at the following conclusions:

*First.* That strophanthus has a distinct action, like digitalis, in increasing the force of systole, at the same time diminishing the rapidity of the heart's action, whether by stimulation of the organ, or direct action upon the heart muscle, he is not prepared to say.

*Second.* That it has little or no effect upon the bloodvessels; and, therefore, causes less blood-tension than digitalis, which, either by vaso-motor influence or direct action, or both, causes a contraction of the vessels, with a consequent rise of blood-tension.

*Third.* That it causes less gastro-intestinal disturbance than digitalis.

*Fourth.* That it possesses, like digitalis, both antipyretic and diuretic properties.

*Fifth.* That, unlike digitalis, it is not cumulative in its effects; and

*Sixth.* That it may be used in smaller doses than digitalis.

If Fraser's conclusions prove true in practice, we find a decided weight in the balance in favor of strophanthus; and, although experience teaches us to be cautious in accepting the much-vaunted virtues of any new remedy, yet the facts brought to our notice by one of such eminence should make us unhesitatingly experiment for ourselves.

Fraser has used *strophanthus* in the form of a tincture, in doses varying from three to twenty minims, twice or three times daily; but, in a recent article, he speaks of the dose as varying from five to ten minims. He has also experimented most successfully with the subcutaneous injection of the active principle, *strophanthin*, a glucoside, in doses of  $\frac{1}{10}$  of a grain; and, by this means, has noticed much more lasting effects from one dose than with the tincture. In one case, with severe symptoms from mitral regurgitation, the marked beneficial effect upon the heart's action by a

single subcutaneous injection of  $\frac{1}{10}$  gr. of strophanthin was noticed for eight days.

In the *New York Medical Record* of December 18, 1886, among the "Transactions of the Practitioners' Society of New York," are reports of cases by Dr. C. L. Dana, the only ones yet made public, so far as I know, in America.

Dr. Dana's results, in a comparatively small number of cases, are such as to make him believe that strophanthus, as now used here, is a valuable addition to our pharmacopœia, and can be often used in cases where digitalis is not so efficacious.

The testimony of other observers seems to point towards the favorable action of strophanthus, some believing that, eventually, it will supersede digitalis in the treatment of heart disease.

My attention was especially called to the drug by a well-known lady physician of this city, who is enthusiastic over its action in her own case, and has kindly allowed me to quote her experience with it:

During the previous year, this lady, a sufferer from a mitral lesion, was very ill, in the south of France, with pneumonia, during the progress of which the heart became very troublesome. At the suggestion of her physician, during her convalescence she began taking strophanthus; and, before twenty-four hours had passed, experienced the greatest relief from the breathlessness upon the least exertion, which had been one of her most distressing symptoms. The improvement continued steadily, until, by the advice of a physician in another part of France, she ceased to take strophanthus, when the former symptoms returned. Repeated experiments have shown her conclusively that the drug gives her great relief from dyspnea, and its effects are always more pleasant than those of digitalis. In the use of the latter she had always experienced a depressing effect, coupled with gastric disturbance; with strophanthus, however, the effect is always rather exhilarating, and it has never caused the slightest trouble with the digestion. Its action is always markedly diuretic; and, although she has never taken it in doses sufficiently large to carry the pulse below the normal rate, it has always had a distinctly calming effect upon the heart. She continues to use the drug, omitting it at times for a few days, and always experiences the same sensations upon resuming it again. Her testimony, therefore, is distinctly in favor of strophanthus as a substitute for digitalis.

Acting upon these suggestions, I was, fortunately, able to try the drug in a case of severe heart disease, transferred to me by Dr. F. I. Knight, in which a slight mitral systolic murmur, great dilatation of the left ventricle, pulmonary œdema, a very rapid, irregular, intermittent pulse, and almost constant orthopnea, were the chief symptoms. For several weeks, almost constant use of the tincture of digitalis, and trials of sparteine and caffeine, had failed to effect the action of the heart muscle, the pulse varying from 140 to 110 to the minute most of the time. Tincture of strophanthus, in doses of about three or four minims, three or four times a day, was tried; but, owing to some rather obscure symptoms, which I then thought might arise from the drug, it was discontinued after the third or fourth day; and although the patient insisted that she liked the medicine, and that she breathed more freely, I noticed no special action upon the heart or pulse.

Soon after this, the patient developed signs of con-

gestion in the lower part of the left lung, namely, dullness and slightly bronchial breathing; râles from rapidly increasing pulmonary oedema were heard on both sides; the legs, arms, and face were swollen, the dilatation of the heart increased and relief from great dyspnoea was obtained only by subcutaneous injections of morphia.

The husband of the patient having heard that Dr. M. L. Chamberlain of this city had had experience with strophanthus, suggested a consultation to which I gladly assented, and at his advice the strophanthus was again tried and gradually pushed. It was given finally in doses from fifteen to twenty-three drops by the ordinary glass dropper (about equivalent to ten or twelve minims) three or four times in the twenty-four hours; digitalin, in doses varying from gr.  $\frac{1}{16}$  to gr.  $\frac{1}{8}$ , being given between the doses of strophanthus when the patient was awake. It would be quite unfair to attribute all the gain which immediately followed to strophanthus, for although digitalis as used before in the tincture had not had the slightest apparent effect upon the pulse, yet the use of digitalin naturally makes it impossible to say which was the larger factor in the improved condition of the patient, but the following facts were noticed: rapid decrease of the dullness and bronchial breathing over the congested portion of the left lung, great diminution in the number of râles throughout the chest; the swelling of the arms and legs diminished, the dyspnoea was less marked; the action of the heart became much less feeble, while the pulse slowly dropped from 120 to 88, became perfectly regular and lost its intermittent character. This improvement continued for about a week, when a curious friction sound appeared near the angle of the left scapula, the exact nature of which it was impossible to determine, and that night, the patient while sitting up during a movement from the bowels suddenly fell back and expired. No autopsy was allowed.

*Synopsis of case.*—Patient suffering intensely in the last stages of mitral disease, after receiving no apparent benefit from the tincture of digitalis, sparteine or caffeine, obtains very great relief from somewhat large doses of tincture of strophanthus alternated with digitalin.

Another case in which I have noticed a markedly beneficial effect from strophanthus is a lady sixty-three years of age, for years a sufferer from valvular disease in which dyspnoea and great irregularity of the heart's action are the chief symptoms. During a severe illness last November, from which I never expected her to recover, all the most serious symptoms were greatly relieved by three or four minims of strophanthus given three times a day. General oedema of the legs disappeared; the action of the heart and pulse steadily improved and the latter, which by the use of digitalis had fallen to about 45, rose again to about 60, and although occasionally intermittent was more regular than I had ever known it under the previous use of digitalis. The patient is now vastly improved in health, moves about the house, is able to go out to drive or walk, and still takes about three minims of the strophanthus three times a day, and although the pulse still intermittes and is somewhat irregular, the action of the heart is much less tumultuous than before, and varies from 65 to 80 beats in the minute.

The last case in which I have used the drug is a

man about fifty-eight years of age, who has had symptoms which point to fatty degeneration of the heart, namely, a weak, rather irregular and rapid pulse with occasional attacks of faintness. This patient seems not at all sensitive to the drug, and I have gradually increased the dose to fifteen minims, four times in the twenty-four hours. Although the pulse has never fallen below 86 and usually is about 94 or 96 to the minute, it is now of very good strength and perfectly regular ever since he began to take the tincture about five or six weeks ago. Previously the pulse had often been above 100, and at times very weak. The general condition has slowly improved; there has been no recurrence of the attacks of faintness, and as the patient tells me he has always had a rapid pulse I have not attempted to reduce its action farther, and am at present diminishing the dose again to see how far the drug has a controlling action upon his heart.

From such a meagre array of cases I should, of course, be unjustified in making any remarkable claims for the drug, but the experience of others combined with the results of my own observation, makes me feel it should be brought before the profession and tested.

As to the preparations now in use in this country, I only know of the tincture and the soluble triturate tablets as prepared by Fraser & Co., of New York, in which one tablet represents one minim of the tincture.

I have reasons for believing that the tinctures which I have thus far tried, made by some of our best-known firms here, are not yet of as good a quality as those prepared by Prof. Fraser or by Messrs. Duncan and Flockhart, of Edinburgh.

Through the kindness of the lady-physician already referred to, I have seen the Edinburgh preparation, and instead of having a greenish hue, it is colorless, has a slight but distinct odor of sulphuric ether, leaves no precipitate when added to water, and has a less bitter taste than these tinctures which I have seen here.

I can but think, moreover, that our present preparations vary in their strength; a fact which makes thorough experimentation much more difficult, but by keeping in mind the same general principles which guide us in the use of digitalis, chiefly watching the character of the pulse, we shall be enabled to test the comparative value of strophanthus, with little danger of doing harm.

It is to be hoped that before long we can make experiments with the active principle strophanthin which Fraser tells us is a much more efficacious method of administering the drug than any other.

Increased facilities for obtaining the plant from Africa will doubtless before many months not only enable our druggists to give us this form of strophanthus, but at a greatly reduced price.

## REPORT ON THE PROGRESS OF SURGERY.

BY H. L. BURRELL, M.D., AND H. W. CUSHING, M.D.

## CEREBRAL SURGERY.

THERE have been a few important contributions to the surgery of the brain. Mr. Victor Horsley's paper<sup>1</sup> read at the last annual meeting of the British Medical Association, gives the details of operating on the brain and the dangers that arise in the after-treatment of such cases. The following cases are recorded, all of which were successful. Two trephinations for traumatic epilepsy; the removal of a tubercular tumor from its previously located position at the junction of the lower and middle thirds of the ascending frontal convolutions. The cases of Mr. Horsley, Dr. Clark, of Glasgow, and the recent case of Hughes Bennett and Pearce Gould<sup>2</sup> seem to indicate that trephining for traumatic epilepsy, is becoming an established operation; it is certainly a justifiable, although not always a successful operation. On the other hand, the removal of tumors from the brain substance is not as encouraging. Four cases have been recorded; the case of Mr. Godlee<sup>3</sup> and Dr. Bennett, which cannot be regarded as successful, a case by Dr. Kirschfelder, of San Francisco, in which death occurred on the seventh day; Mr. Horsley's successful case; and the successful removal by Dr. Durante, of Rome, of an endocranial tumor from the base of the skull.

Of interest from a practical point of view is the London Pathological Society's exhibit of cerebral tumors<sup>4</sup> in which out of forty-four specimens of intracranial growth, only two would be suitable for an operative attack.

## COMPRESSION OF THE BRAIN.

E. VON BERGMANN in a recent report,<sup>5</sup> states that the mechanical action in compression of the brain, is similar to progressive cerebral anemia from other conditions. That the blood is driven from the capillaries by pressure, as water from a sponge, causing impaired nutrition, the effect of which is first irritation and subsequently paralysis of the nerve centres. Thus the pulse at first, through irritation of the vagus, is retarded, but later, when paralysis of the latter occurs, becomes more accelerated. For his reasons in detail, the reader is referred to the original article; which is also valuable from its reference to the latest advances in closely related subjects.

## A NEW CONTRIBUTION TO THE STUDY OF CRANIAL AND SPINAL INJURIES.

DR. B. VON BECK<sup>6</sup> during the last two years the author has investigated one hundred and eighty-two cases of injuries of this nature, of which number, one hundred and seventy-five occurred in military, and seven in civil practice. Twelve cranial, and thirteen spinal injuries are reported in detail with full comments on the cases. He contrasts briefly the symptoms of pure commotio cerebri with shock, excluding from consideration those so-called mixed cases of concussion, in which associated with the conditions of concussion dynamic or structural disturbances by rupture

of the connection between the delicate vessels of the meninges and the brain itself, are followed by hemorrhage. The latter may be very slight, and generally occur in the cortex, rarely in the deeper-situated vascular tracts. In regard to cortical centres, v. Beck adopts the view that these are, indeed, the terminations of different conduction-paths, but that by abundant anastomoses impressions are rapidly transferred to neighboring structures, which act as substitutes; and disapproves an extensive localization of individual smaller circumscribed cortical centres.

After a short enumeration of the disturbances of motor and sensory functions observed in all the severer spinal injuries, the author mentions the participation of the vaso-motor nerves, which are always present when the gray substance of the cord is involved. Priapism is a cardinal symptom. Other symptoms which subsequently soon appear, and can be ascribed only to a vaso-motor paralysis, are delayed capillary circulation in the paralyzed limb, dilatation of vessels and consequent slight edema of skin and subcutaneous tissues, and a slow return of normal color of the skin after circumscribed pressure. Elevation of temperature of paralyzed areas. Trophic disturbances accompany these vaso-motor changes hand in hand, as is shown by a predisposition to pressure gangrene, and atrophy of tissues, especially muscular. For a full analysis of the symptomatology the reader is referred to the original monograph. In regard to the treatment of these injuries the following brief synopsis of the author's opinions and experience, is especially of interest. Three complications appearing soon after the injury are particularly dangerous to life, namely, decubitus, myelitis with its sequelae, and purulent cystitis, the prophylaxis and treatment of which is given in detail. In fractures of the spine, v. Beck discountenances all extensive manipulations, which he claims are, as a rule, detrimental, and seldom of value.

## OPERATIVE TREATMENT OF EMPYEMA OF THE ANTRUM HIGHMORE.

The disadvantages of an artificial opening in this affection in the roof of the oral cavity as heretofore made, are that the opening is not always permanent enough (the suppuration sometimes lasting for years), and the easy access of particles of food to the antrum, thus prolonging or aggravating the suppurative process. To avoid these, Mikulicz<sup>7</sup> proposes to establish the opening for drainage in the lower nasal passage at the level of the inferior turbinate bone. The inner wall at this point is quite thin, and easily perforated by a short-bladed stylet. By cutting downwards and forwards, no harm is done, for the wall here becomes thicker and resists the instrument. Too free hemorrhage is controlled by iodoform gauze tampons. The after treatment consists in washing out the antrum with a balloon syringe having a curved nozzle. He found the operation easy on the cadaver, but an abnormally narrow nostril or excessive thickness of a turbinate bone might render it impracticable.

In a man aged thirty-three, affected for several years with empyema of the antrum, this treatment proved successful in four weeks.

## OPERATIVE TREATMENT OF CLEFT PALATE.

J. Wolff<sup>8</sup> reports twenty successful cases in which

<sup>1</sup> British Medical Journal, October 9, 1886, p. 670.<sup>2</sup> British Medical Journal, January 1, 1887, p. 12.<sup>3</sup> British Medical Journal, May 16, 1885, p. 988.<sup>4</sup> British Medical Journal, February 6, 1886, p. 240.<sup>5</sup> Arbeiten aus der chir. Klinik der Königl. Univers. Berl. I, Th. I.<sup>6</sup> Annals of Surgery, Aug., 1886.<sup>7</sup> Deutsche Ztschr. f. Chir. Bd. xxiv, 1-150, 1886.<sup>8</sup> Centbl. f. Chir., 1886, No. 24.<sup>9</sup> Arch. f. Klin. Chir., 1886. Bd. xxxiii, Hft. 1.

he has closed the palatal defect by operation correcting at the same time any existing labial and nasal defects. The after-treatment consists in fitting the patient with a vulcanized soft-rubber obturator,<sup>10</sup> and training the wearer in use of the voice until power of speech is fully acquired. Eventually the person may learn to talk without it. He recommends operating with the head dependent, and emphasizes the importance of minimizing the amount of hemorrhage, which he controls by uninterrupted firm pressure of from two to four minutes with pledgets of salicylated gauze held *in situ* by the finger or spatula. During the operation (and for the first few days following) the whole oral and pharyngeal cavities are irrigated with a tepid salicylic solution which the dependent position of the head renders possible, and diminishes the amount of swelling of the wound edges. The advantages of this method claimed by Wolff, are the diminished amount of hemorrhage, the opportunity for irrigation, which aids greatly rapid union, the rapid acquirement of good power of speech, and its adaptability not only to adults but also to young children.

#### REMOVAL OF CARCINOMA OF THE MOUTH, ISTHMUS OF THE FAUCES AND PHARYNX.

After a short review of a full report of twenty operations for the removal of wide-spreading cancer of the mouth and pharynx, in addition to eighteen unoperable cases, Polaillon<sup>11</sup> gives the following conclusions: (1) That pneumonia is a very dangerous sequela of extensive operations of the mouth and pharynx. (2) The chief danger is hemorrhage. (3) That antiseptics is the best safeguard against the former and preliminary ligation of the carotid (double ligature and division of vessel) against the latter, not only at time of operation, but also secondary. (4) That preliminary tracheotomy is indicated only where asphyxia is to be feared during the operation. Its prophylactic value against pneumonia is doubtful. Polaillon agrees with Verneuil that non-closure of the facial wound and through antiseptic irrigation are of far greater value against this danger. Of Polaillon's twenty cases subjected to operation, one died from syncope at the end of the operation, three from hemorrhage, two from sepsis, two from pneumonia; total eight.

#### INFECTIOUS SUBMAXILLARY CELLULITIS.

Paul Tissier<sup>12</sup> records two cases of Ludwig's angina, and elaborately reviews the subject.

It manifests itself in persons between twenty-five and thirty years of age, and frequently occurs after exposure to cold.

After three days of prodromata, the neck becomes swollen and painful. The tongue is so swollen that it is immovable, the buccal mucus membrane is reddened and there is great salivation. The mouth can hardly be opened owing to the swelling of the neck, and the chin is obliterated. At the end of a week, after marked oscillations of temperature, suppuration or gangrene occurs.

The disease is a grave one, an infectious process of a septic character, and is supposed to be due to a lesion of the buccal cavity, through which the germs enter the tissues between the chin and hyoid bone.

#### CICATRICAL STENOSIS OF THE TRACHEA.

Küster<sup>13</sup> reports the following classification of the above tracheal affection, which he divides into four groups according to its origin:

- (1) Traumatic, resulting in a majority of cases from attempts at suicide.
- (2) Syphilitic.
- (3) Neoplastic, sarcoma and carcinoma.
- (4) Diphtheritic most common.

(a) "*Granulation*" stenosis, generally at upper border of wound, due to a certain predisposition in addition to the irritation from the tube. Appears at times in form of a "granuloma" of the mucous membrane after cicatrization of the external wound. (b) *Submucous stenosis* caused by a puckering of the mucous membrane into transverse or longitudinal folds, and depressions by the submucous scar-tissue. The resulting chronic inflammation can cause softening of the cartilage and extend into the peritracheal tissue. (c) *Mucous stenosis*, most severe and also the rarest form, generally fatal.

Of the diphtheritic form Küster has collected from among 709 tracheotomies, 17 cases of stenosis. Of these 12 were successfully treated, 3 were discharged not cured, 2 terminated fatally; one from chloroform, the other from a peritracheal abscess. The treatment consisted in opening the trachea, and removing all granulation tumors, bands, or folds. The trachea was then kept patent by a systematic dilatation through the opening. In traumatic strictures a partial excision of the trachea is claimed to be the only means of obtaining a permanent cure.

#### OPERATIVE TREATMENT OF PULMONARY ECHINOCOCCUS.

J. Isreal reported a case of echinococcus of the lung, treated successfully by operation. From personal experience and from the reported cases of Schede, Cornil and Gibier, he concludes that treatment by incision and drainage, in the manner described in the report, is attended by far less dangerous consequences than an exploratory puncture which in three cases was followed at once by death from suffocation, in consequence of the cyst rupturing into the bronchi. In all three cases this rupture resulted from violent paroxysms of coughing, which the puncture caused. Hence it is of great importance that puncture should not be attempted until this reflex irritability has been controlled by morphine or chloroform narcosis. The latter is preferable if a radical operation can be at once performed. The details of the operation are fully described.<sup>14</sup>

#### RESECTION OF THE THORAX IN REMOVAL OF TUMORS OF THE CHEST-WALL.

Prof. H. Maas<sup>15</sup> has discussed this procedure, and after reporting three cases gives the following conclusions:—

- (1) That in aseptic operations and after-treatment, even where large portions of the ribs and costal pleura have been removed, a rapid expansion of the collapsed lung can occur without inflammation or inflammatory adhesions of the parietal with the visceral pleura, or with the soft parts used to cover the defect.
- (2) That the two great dangers from opening the pleural cavity and exposing the lung, namely, loss of

<sup>10</sup> Arch. f. Klin. Chir., Bd. xxv, p. 898, 1880.

<sup>11</sup> Gaz. de Par., lvi, 29-31, 1886.

<sup>15</sup> Arch. f. Klin. Chir., Bd. xxxiii, Hf. 2, 1886.

moisture by evaporation, and sudden cooling of the exposed thoracic organs, can be avoided by the use of a steam-spray.

(3) That irrigation of the thoracic organs should be avoided, if possible, and when necessary, a non-irritating solution (salicylic acid) of the temperature of the body should be used.

#### STRICTURE OF THE OESOPHAGUS.

The treatment of this affection is again called to notice by Maydl.<sup>16</sup> The various methods adopted, since the operation of gastrostomy has furnished an opportunity of attacking a stricture from below, show a gradual improvement of the efficiency of surgical interference in these cases. Rejecting the old method of attempting dilatation *per orem*, the gastric opening was utilized to pass bougies through the stricture from below upwards (Bergmann, Schattauer). Others have used the gastric fistula to pass a thread from the mouth through the oesophagus to the artificial opening by passing a slender sound through from above and by means of this thread dragging into place the selected instrument, (rubber drainage-tube Weinlechner and v. Häcker, bougies, etc.), by which the actual dilatation of the constriction was to be accomplished. Maydl has introduced an apparently much improved method in that having once succeeded in finding a passage through the stricture it is never lost till the dilatation is complete. Briefly described, the operation is as follows. A small bougie, No. 5, to the upper end of which is attached a strong double silk thread twice the length of the bougie, is passed down the oesophagus and pulled out through the gastric opening by seizing its tip as it projects from the cardiac orifice with a pair of forceps, introduced for that purpose. The oral end of the thread is now fastened to the tip of a No. 10 bougie, which is drawn carefully down into the stricture, so that its upper end (to which a thread similar to the first is attached) is well in the oesophagus. This remains *in situ* twenty-four hours, and is then withdrawn, by means of the lower thread, through the gastric opening leaving the upper thread in its place, by which the next bougie could be drawn into position. The bougies are allowed to remain *in situ* twelve hours; and a larger one is introduced every second day. As the dilatation progresses the period of actual dilatation is diminished with each successive instrument. A small amount of cocaine (five per cent. solution) exhibited *per orem* reduces the irritation from manipulation. Introduction of the thread through the nose causes less irritation than through the mouth. In Maydl's patient this method caused a rapid improvement, and was far superior to the old system in rapidity of effect. It seems well adapted to the treatment of oesophageal strictures, cicatricial and non-malignant in character.

#### A NEW METHOD OF GASTROSTOMY.

The difficulty in preventing the escape of the contents of the stomach after gastrostomy is well known; and also how unsatisfactory, as a rule, are the numerous appliances devised for this purpose. Again, the rule of making the fistula as small as is possible, and allow the introduction of food, fails to remove this annoyance. The continual discharge also keeps the edges of the wound in a state of ulceration. After

describing a number of the most efficient means of meeting this difficulty, and stating their disadvantages, v. Häcker<sup>17</sup> proposes to solve the problem by placing the wound of operation two and one-half to three cm., to the left of, and parallel to the linea alba, so that after the operation the powerful contraction of the rectus muscle shall, by enclosing the opening in its fibres, act the part of a sphincter. Another advantage claimed is, that the incision of the rectus in the direction of its fibres and subsequent suturing of the peritoneum to the skin makes it more difficult for the gravitation of pus to occur between the muscular planes of the abdominal wall, and is more favorable to primary union, than when it is cut obliquely or transversely. After giving the arguments why this situation is equally as advantageous as the "Fenger" incision which is regarded as the most practical and is most commonly employed (one finger-breadth from, and parallel to the left costal arch), and quoting Hyrtl, Langer, Henle, Luschka and others as his authorities for his statements in regard to the anatomical position of the stomach in relation to the abdominal wall and to the proposed seat of operation, v. Häcker describes in detail a case in which this plan had been practised. The indication for gastrostomy was the existence of a very narrow stricture of the oesophagus near the cardiac orifice caused by carcinoma. The operation was as follows. The abdominal incision was eight cm. long, commencing at a point one finger-breadth from the left costal arch, two and one-half cm. from the median line, and parallel to it. After opening the rectus sheath, and dividing the muscle by separating the fibres with a blunt instrument, the peritoneal cavity was opened. The stomach appeared in the wound. A fold of the anterior wall above the fundus was drawn out of the incision and held in position by transfixing it with a needle, the ends of which rested on the external surface of the edges of the abdominal incision. After suturing the edges of the parietal peritoneum to the skin, at the seat of the proposed fistula, and closing the abdominal wound above and below this point, the stomach wall was fastened to the wound by eighteen sutures passed through the serous and muscular coats, so as to close the peritoneal cavity. For greater surety, several of these included the skin. Iodoform gauze dressing. The following day the needle was removed. Two days later the exposed surface of the stomach was divided, the mucous membrane and skin united by suture, and the patient fed through a medium-sized drainage-tube inserted in the opening. On account of the escape of the contents of the stomach an especially devised obturator was substituted. The patient was convalescent in four weeks, and until his death, two and a half months after the operation, from extension of the carcinoma to the lung, his condition was much alleviated. The fistula showed no signs of dilating, and thus a continual change to larger-sized tubes to prevent leakage, as commonly occurs, was avoided. After the wound had healed, the opening could be closed by approximating its sides laterally by a strip of plaster. If left entirely open the gastric contents escaped on reaching the level of the opening, especially in an erect attitude. The dissection of the rectus muscle parallel to its fibres causes far less hemorrhage than when these are divided transversely. Dissections on the cadaver show that if the fistula is established in the upper

<sup>16</sup> Ueber ein neues Verfahren der dilatation von Narbenstricturen des Oesophagus bei vorhandener Magenfistel. Allg. Wien. Med. Ztg. June 15, 1906.

<sup>17</sup> Wien. Med. Wochenschr., xxxvi, No. 31-32.

part of v. Hacker's proposed incision, its site exactly coincides with that of the "Fenger" incision, the latter intersecting the former in its (v. Hacker's) upper one third. It was also found that the stomach was easily accessible. The incision of the rectus should be between the highest and next inferior linear transverse.

(To be continued.)

### Clinical Memoranda.

#### A CASE OF HYDATIDIFORM MOLE.<sup>1</sup>

BY JAMES R. CHADWICK, M.D., BOSTON.

AMONG the cases of "Congenital Stenosis of the Female Genital Tract" published by me in the *Boston Medical and Surgical Journal* of June 3, 1886, was one (Case 3) in which there was an almost complete closure of the vagina just in front of the cervix uteri, which was entirely relieved by operation, when the patient passed from observation seven years ago. I was summoned to see her in consultation with Dr. A. E. McDonald, of this city, on June 6th, when I learned the following facts of her subsequent history. A healthy child had been born to her eighteen months ago; from the eleventh month of lactation, menstruation had recurred regularly until April 22d, the day on which she weaned her child, when it failed to appear. She had no special symptoms until May 7th, when her child was taken ill and she began to pass a small quantity of watery blood, which recurred in the subsequent four weeks almost every time she lay down. From that date the vomiting was very frequent and severe. Dr. McDonald was called about June 1st, when she passed a considerable clot. He found the uterus enlarged systematically, almost to the naval, and the vomiting controllable only by frequent doses of morphine. On June 6th, eleven weeks after the last menstruation, I found the patient in good physical condition with the temperature below 100°F., but the pulse 140-150. The vomiting was so frequent that scarcely anything was retained on the stomach. The pregnant uterus rose an inch above the navel, no fetal parts could be felt and no fetal pulse or placental bruit heard: the aortal pulse was, however, transmitted with remarkable distinctness. I was unable to reconcile the size of the womb with the data as to menstruation given by the woman. The size of the womb corresponded with the sixth month of gestation, yet at that period the fetal parts and heart sounds should have been recognizable. The cervix was not soft, but exhibited a deep laceration on the left side, from the angle of which a cicatricial seam extended across the vault of the vagina. The lips were everted and granular; the touch caused the granulations to bleed freely, so that I cauterized them with nitrate of silver under the impression that the hemorrhages might be attributable to that source, as in a case I had recently seen. No diagnosis was made then, but that afternoon it suddenly flashed into my mind that the manifestations of the case were identical with those of the case of hydatidiform mole reported by Dr. W. L. Richardson at the last meeting of this Society; the omission of two catamenia, the repeated sero-sanguineous discharges from the sixth to the eleventh week, the sudden enormous development of

the uterus without evidence of a fetus, the incessant vomitings. No cysts had, however, been evacuated. I accordingly wrote to ask Dr. McDonald to meet me at the patient's house on the second day after (June 8th), when we found that the woman had been vomiting incessantly for the past twenty-four hours; she was much exhausted and had a weak pulse of 140-150. Dr. McDonald administered ether and I tried ineffectually to pass my finger through the inner os. The cervix was rigid and unyielding, so that I had to resort to Goodell's dilator to open the canal. Though this was done very slowly and carefully, I soon recognized that the cervix was splitting in the line of the former rent. When dilatation was sufficient to admit my finger into the interior I could feel the smooth surface of a blood-clot. Dilatation was continued by the fingers alone for about fifteen minutes longer, until three fingers could pass into the interior, when fresh hemorrhage became so profuse that prompt evacuation was manifestly imperative. The hand was passed into the vagina and after a few efforts into the womb. Handful after handful of cysts held together by blood-clots and chorionic membranes, were thrown out into a basin while fresh blood streamed from the vagina. Within thirty seconds the uterine cavity was empty and the fundus, stimulated by the manipulations of the other hand through the abdominal wall, contracted at once and permanently. The hemorrhage, however, continued, though less profusely. Hastily inserting a speculum I saw the blood issuing from a deep rent in the cervix and the vaginal vault on the left side which opened into the pelvic cellular tissue. This was promptly arrested by a tampon of cotton soaked in a solution of perchloride of iron. The pulse was now found to be nearly imperceptible, but came up under repeated subcutaneous injections of brandy. The convalescence has since been slow. The next morning Dr. McDonald and I removed the tampon, washed out with a solution of permanganate of potash the blood-clots formed by the iron, and placed a suppository of iodoform in the rent. On the second day, when I was at Providence, she suffered for twelve hours from exhausting vomiting which was skillfully checked by Dr. McDonald, who, I should say, has had the chief care of the patient. To-day, the patient was comfortable, had no vomiting, no inflammation; a temperature of 101°F, but the pulse still 140. She bids fair to recover. With regard to the ulceration of the cervix and vaginal vault in the line of the old cicatrix, I believe the mishap to have been unavoidable in the emergency and moreover, to be of not infrequent occurrence. I have certainly seen it once before when speedy delivery of a child was necessary to save a patient's life threatened by inter-partum hemorrhage. The bleeding from the ruptured vessels in the cellular tissue, was in that case arrested by a tampon soaked in an iron solution. No bad symptoms followed and the fissure healed, so that finally a small notch in the cervix and a cicatrix across the dome of the vagina alone indicated the extent of the rupture.

The following letter was received from Dr. McDonald:

DEAR DOCTOR.—The patient recovered quite well from the shock of the operation, but remained for some time weak and restless. Pain was not at any time prominent nor did she have much hemorrhage. Her stomach was very irritable, with a tendency to vomit; she was, therefore, fed by enemata for the first two weeks. A douche of solution of permanganate of iron

<sup>1</sup> Read before the Obstetrical Section of the Suffolk District Medical Society, June, 1886.

was continued during that time. One week after operation she developed cellulitis starting from the point of rupture in the os. The temperature ranged about 102 F., but never got above that point. In the course of the cellulitis she suffered a severe attack of acute nephritis, which induced persistent vomiting.

On the third day of July, I discharged her comparatively well. I have not seen her since that time until to-day, September 11, 1886, I find her looking well and robust. She considers herself in very good health, and complains of nothing but a slight yet continuous oozing of dark blood. The fact that she is menstruating precludes a vaginal examination.

Yours very truly, A. E. McDONALD, M.D.

### FRACTURED TRACHEA.

BY E. C. FORTON, M.D.,  
Assistant Resident Physician, Tewksbury Almshouse.

JANUARY 31, 1887, a robust Irish-American, aged twenty-eight, a bricklayer, was admitted to State Almshouse Hospital, at Tewksbury, complaining of pain and soreness in the throat.

When first seen, his throat was considerably bound up with flannels, but the portion exposed indicated great swelling and redness. On being questioned, the patient said he had fallen, two days before, through a staging, striking his throat on a portion of the staging that did not break.

Placing my fingers on his neck, I easily detected emphysema, which, I found, on further examination, extended to border of the lower ribs in front and sides, and down the back as far as lower borders of the scapulae. The pupils were considerably dilated, though the patient claimed he had taken no medicine that day; the slightest handling of the trachea caused spasmodic breathing for a moment, although, at all times, breathing was slightly hurried and difficult; the voice was clear, but not strong.

When asked to locate the seat of injury, the patient placed his finger just below the cricoid cartilage. External digital examination proved that the hyoid bone was still intact; and the ability to articulate distinctly eliminated from my mind any possibility of injury, either to the thyroid or cricoid cartilages, and compelled me to believe that either one of the upper rings of the trachea was fractured; or the membranous structure between the rings, or the muscular tissue behind, was ruptured. No examination which the patient's condition would allow me to make, owing to the excessive amount of air in the tissues about the neck, enabled me to locate just where, in the upper part of the trachea, the injury took place; but we know that when a hoop is pressed together at two opposite points, the other two opposite points, that is, the sides, are the places where the hoop breaks; and, inasmuch as the emphysema was about equal on both sides of the neck, it is easy for me to conclude, since the blow in this case was on the front of the tracheal rings, that the upper ring, or first two rings, perhaps, was broken at the sides, so as to allow air to escape into both sides of the neck.

Patient related that, for the first twenty-four hours after the injury, his struggle for breath was very trying; swallowing of liquids, even, caused a great deal of pain; and that he bled freely for several hours after injury. There was considerable bronchitis present at the time of admission, and his sputa were quite bloody; both bronchitis and blood-sputa lasted for seventy-two hours. There was, at no time, oedema of the glottis.

*Treatment.* Patient was put to bed, and enjoined

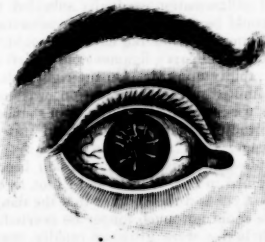

to keep his head as quiet as possible; given ten grains of calomel, which was followed, in six hours, by an enema of suds, free movement of the bowels resulting. The cold-pack was applied to the neck, and maintained for forty-eight hours. Other medication consisted in relieving the bronchitis, and a few doses of morphine, at night, to insure sleep.

The following I quote from my clinical book: February 2d. Patient more comfortable; less emphysema, less cough. February 4th. Emphysema diminishing; also soreness in the throat; swallowed liquids without much pain. February 8th. Only slight emphysema, which is at top of sternum. February 12th. Since last record no emphysema could be detected, and there is now no difficulty in swallowing solid food. Patient had apparently made a complete recovery.

### PERSISTENT PUPILLARY MEMBRANE.<sup>1</sup>

BY CHARLES S. TURNBULL, M.D., OF PHILADELPHIA.

I HAVE brought before you to-night a case of unusual interest to ophthalmologists and to medical men in general. The patient has in his right eye what is known as a "persistent pupillary membrane." This is a remnant of fetal life, but its exact structure has not been ascertained. Some consider it to be made up of atrophied bloodvessels, which have served their purpose. Other authorities hold that it consists of the remains of connective tissue through which bloodvessels pass. In this man's right eye there is a network of hair-like fibres occupying the outer half of the pupil. These fibres originate from the anterior surface of the iris, and interfere in no way with the constrictor muscle of the pupil. This form of congenital anomaly was first observed about 1735, and on an average about one case has been reported every five years since that time. I am indebted to Dr. P. H. Bailhache, of the U. S. Marine Hospital Service, for the opportunity of exhibiting this patient.

[In the subsequent discussion, Dr. E. Jackson said: This case is notable for the clearness with which it shows the relation between the membrane and the iris. In all the cases I have seen heretofore, as in this, the pupillary membrane has seemed to arise from the anterior surface of the iris; but in no other instance has the connection been so obvious, the membrane here appearing to be simply an extension of the anterior layer of the iris, and similar to it in structure.

<sup>1</sup> Read before the Philadelphia County Medical Society, at the Stated Meeting, February 23, 1887.

Dr. Turnbull said that the point referred to by Dr. Jackson is well illustrated in this case, and it settles the disputed question as regards the origin of these fibres. It is distinctly seen that the sphincter muscle is in no way involved. The membrane has no connection with the muscle nor with the inner pupillary margin.]

### Reports of Societies.

#### BOSTON SOCIETY FOR MEDICAL IMPROVEMENT.

E. M. DUCKINGHAM, M.D., SECRETARY.

\* FEBRUARY 14, 1887. The President, DR. O. F. WADSWORTH in the chair.

#### OVARIAN CYSTOMA OF RAPID GROWTH, CAUSING SEVERE PERITONITIS AND INTESTINAL OBSTRUCTION.

DR. JAMES B. AYER reported the case:

Mrs. B., forty-two years; fifteen weeks before was suddenly seized with severe pain in each groin. Examination next day showed a prominent swelling corresponding to the transverse colon, together with peritonitis; pain most marked in inguinal regions. Morphia prescribed.

The bowels gradually became obstructed. At the end of four weeks, there were marked tympanites, delirium, nausea with vomiting, and severe pain, requiring two grains or more of morphia daily. There was no defecation for eight days.

These symptoms strongly suggested obstruction from malignant disease.

By Dr. Warren's advice, he having seen her in consultation at different stages, the transverse colon was punctured with a fine trocar, and croton oil and enemata were freely used. The distension was much relieved by puncture and the bowels were opened on the ninth day—the pressing symptoms were relieved, and there was no serious trouble afterward from obstruction. Peritoneal inflammation gradually subsided until the abdomen could be examined to better advantage.

A small lump of stone-like hardness could be made out just above Poupart's ligament on the left side, and this grew rapidly upward. On the right side, after a while, a limited area of fluctuation was made out. When this was evacuated a hard lump remained.

Dr. Whitney examined the fluid and stated that it probably came from an ovarian cyst. As the cyst rapidly refilled after aspiration, and had become purulent it seemed to Drs. Warren and Elliot, as well as to Dr. James Ayer and the speaker that the danger from this source could not much longer be averted. Moreover, both lumps were growing rapidly, that on the left had passed the umbilicus.

As peritonitis had disappeared, and as she had gained a very little strength from the large amount of nourishment, stimulants and tonics which she had taken, being able to sit up a few moments daily, it was thought proper to insert a drainage tube, and while under ether to remove the tumor if possible.

February 9th. Dr. Warren, assisted by Dr. Elliot, performed ovariectomy skillfully and speedily, and the patient rallied from the operation. For twenty-four hours there were good hopes of recovery, but she sank from septicæmia on the fourth day.

One of the most important among the many inter-

esting points connected with this case according to Dr. Elliot, is the fact that this dense tumor while clinically as malignant as possible, was found by Dr. Whitney not to be pathologically malignant.

DR. WARREN remarked that the condition of the patient when first seen by him was one of typical chronic obstruction. The distension of the abdomen was excessive and the point of constriction appeared to be above the cæcum, as enemata could be made to ascend to nearly that point. It was evident that an attempt made to open the bowel above this region, had such an operation been thought advisable, would not have been successful, owing to the presence of the tumor.

The cyst was tapped the first time for the purpose of relieving pressure. After suppuration had set in, laparotomy was performed, primarily to drain the pus cavity; but it was found impossible to attach the cyst wall to the abdominal wound, owing to its friable character. Notwithstanding the suppurating cyst, the condition of the patient was more favorable at the time of operation than at any moment during treatment.

#### POISONING BY CARBOLIC ACID.

DR. MINOT reported the case of a young married woman who was brought to the Massachusetts General Hospital, February 4th, nine hours after having swallowed, with suicidal intent, about seven fluid-drachms of liquid carbohc acid, stated by the apothecary of whom it was bought to be of the strength of from 90 to 95 per cent. Soon after swallowing the poison she became unconscious, with cold clammy extremities. In about three hours violent vomiting set in; two hours later she became able to speak and to swallow. Small quantities of saturated solution of carbonate of sodium, were administered, but were not retained; eight hours after taking the poison she passed a pint of "black" urine. She was brought to the hospital at 4 P.M., in the following condition: great prostration, urgent vomiting, cold extremities, pallor, intellect confused, no recollection of what had occurred, pulse 114, small and compressible, temperature 99.6°, respiration rapid, shallow, with a few tracheal rales. There was no carbohc odor to the breath, no white streaks about the lips, tongue moist, with white coat, fauces and posterior wall of pharynx somewhat dry, with a white surface. The patient could talk and swallow. Some castor oil which was given was soon vomited. Two ounces of greenish-black urine were drawn off, containing a very slight trace of albumen.

In a few hours the general condition improved, but the patient complained of dryness of the throat and of a burning sensation along the œsophagus; there was much vomiting and retching, with intense thirst, and she was unable to speak above a whisper. The next day there was marked tenderness of the epigastrium and left hypochondrium, and the vomiting persisted; she also coughed and raised mucus. The vomitus was not remarkable except on one occasion, when it contained specks of blood. The patient was very hoarse, and the intense thirst and dryness of the mouth continued. During the following night vomiting gradually ceased, and she could retain iced milk. After this there was progressive improvement, but she was still unable to speak above a whisper on the fourth day, and had some difficulty in breathing. The urine gradually returned to its natural color. On the sixth

day the speech was clear and the patient swallowed without difficulty. She was discharged, well, on the ninth day.

FEBRUARY 28, 1887, the President, DR. O. F. WADSWORTH, in the chair.

DR. W. W. GANNETT showed specimens from the autopsy of a case of

#### ECHINOCOCCUS OF THE LIVER.

The publication of the discussion is reserved until the presentation of the clinical report.

DR. JOHN HOMANS showed an

#### OVARIAN CYST

removed by operation. This cyst which was unilocular, showed evidences of having been multilocular. The patient who had had peritonitis before operation is now doing well.

DR. VINCENT Y. BOWDITCH read a paper on

#### THE USE OF STROPHANTHUS HISPIDUS IN DISEASE OF THE HEART.<sup>1</sup>

and he passed about specimens of the tincture from different manufacturers to show the marked difference in their appearance.

DR. F. I. KNIGHT said that this is a drug that can be more easily tested than some others, because it either has or has not certain definite qualities, the presence or absence of which can be discovered by experiment. Even if it prove to be no better or even not quite so good as digitalis, it is still very useful to have an additional drug for use when that, for any reason, cannot be employed. If it shall prove possible to separate its active principle, so that it can be used subcutaneously and with certainty in cases of heart failure, where we now use ammonia, it will be a great boon.

He had personally used strophanthus in a few cases, and it seems to act promptly and efficiently; but his experience with it is not yet sufficiently large to warrant a definite opinion.

It was proper to say that some of the specimens for sale in this city have been poor ones.

DR. F. C. SHATTUCK said that he had been much impressed by Prof. Fraser's paper on strophanthus and had, immediately after reading it, asked Mr. Metcalf to send for some of the drug. Since its reception he had employed it in six or eight cases, but has not as yet been able to come to definite conclusions as to its merits. In one case he thought he had got toxic effects from it; in two others the drug had seemed useless, perhaps because the dose was not sufficiently pushed. The tinctures of different manufacturers seem at present to differ in strength, which makes it more difficult to carry out satisfactory experiments. The case was mentioned of a little girl of ten, with mitral disease, now under treatment. Several weeks ago, while almost absolute rest was being maintained, the symptoms grew gradually worse, cyanosis increased, moderate external and internal dropsy appeared, the jugulars and the liver pulsated, the stomach rejected everything, the urine fell from ten to two ounces per diem. About eight ounces of blood were withdrawn by leeches over the liver, and that night the child slept well, the next morning eat a large breakfast, and the urine increased to ten ounces. Two days after the leeching two minims of the tincture of

strophanthus were ordered thrice daily, and in the next twenty-four hours the child passed more than 120 ounces of urine. It is not easy to say how much of this is attributable to the drug, how much to the leeching. The drug was soon omitted, but has lately been resumed and gradually increased to six minims thrice daily, without the slightest apparent effect on the pulse. In another case similar results were obtained. Both of these form part of a series which will be reported to the Society at a later meeting in illustration of another point in cardiac therapeutics. To reach definite conclusions with regard to the value of a new drug, time and the teachings of a large number of carefully observed cases are required. Such careful trial strophanthus certainly merits, and the speaker rejoiced that Dr. Bowditch had brought forward the subject.

DR. H. I. BOWDITCH had given strophanthus in a case of old mitral regurgitation with enlarged area of cardiac dulness, dyspnea and weak irregular pulse. An obstruction murmur had recently appeared. The patient had steadily improved since this drug was used, there having been slight improvement twenty-four hours earlier. There is now a simple regurgitant murmur and the apex which was without, is now within the nipple. He had also employed it in a case of rheumatism with cardiac lesions and great dyspnea. This patient was extremely ill and died in four days without relief. The drug in this case came from a supply which was said by one of the previous speakers to be poor. With his present knowledge he should use it if digitalis failed.

DR. F. H. WILLIAMS said that the work done by Prof. Fraser on strophanthus deserves respectful attention, as he is one of the few experimenters who have studied this drug, both from the physiological and the clinical side.

In strophanthus we have undoubtedly a very valuable substitute for digitalis and a much more active substance.

DR. LOGAN, of Liverpool, has suggested that the marked and prompt results obtained by the use of strophanthus are probably due to its great strength, and he has been able to get a similar action from digitalis by using it in large doses, m. x every hour for eighteen to forty-eight hours.

#### MASSACHUSETTS MEDICO-LEGAL SOCIETY.

WM. H. TAYLOR, M.D., SECRETARY.

FEBRUARY 2, 1887.

The meeting was called to order at 12.20, P.M., at the Rooms of the Boston Medical Library Association, by President Winsor. Present eighteen members. Records of the last meeting were read and approved.

PRESIDENT WINSOR, Chairman of the committee on Medical Expert Testimony made a verbal report to the effect that the committee had nearly agreed on the form of a bill to present to the Legislature. Some remarks on the subject were made by members Hurd and Johnson.

ASSOCIATE MEMBER FITZ introduced the following preamble and motion:

It is for the interest of medical examiners to make their reports of autopsies as exact and as comprehensive as possible. Especially, since, at the time of the

<sup>1</sup> See page 223 of this number of the Journal.

examination, it is uncertain what questions may subsequently arise as to the cause and manner of death. The reports should, therefore, be based on some scheme or plan which experience has proved to be the most satisfactory to meet the various conditions which may arise. The most feasible way of producing such comprehensive reports is for each examiner to make his record of the post-mortem examination upon a printed blank or form, which shall indicate the data to be determined and the sequence to be followed.

It is, therefore, moved that a committee of three be appointed to prepare for the consideration of the Society, a form to be followed in returning the record of an autopsy.

The motion prevailed and a committee was appointed consisting of Prof. Fitz, and Medical Examiners Draper and Holt.

MEDICAL EXAMINER DRAPER offered the following resolutions:

*Resolved*, that the Massachusetts Medico-Legal Society expresses its cordial sympathy with all proper efforts to limit and control the growing facility with which civil suits are brought in the courts of this State with unfounded declarations of malpractice as a ground for damages.

*Resolved*, that a committee of three be appointed to cooperate with others, either individuals or societies, in obtaining the relief which the medical profession desires and needs in relation to the evil above described.

MEDICAL EXAMINER HURD seconded the motion for the appointment of a committee, and members Draper, Holt and Johnson were chosen such committee.

MEDICAL EXAMINER DRAPER asked what medical examiners understood by the term "settlement" in relation to the bodies of residents or strangers, and also whether members found it a hardship to collect fees of the Commonwealth in cases of examination of the bodies of strangers.

The questions were replied to by Drs. Hartwell, Pinkham, and Fish, giving some variety of opinion.

Medical Examiner Draper stated that he had sent a bill to the Judiciary Committee of the Legislature, giving medical examiners the power to hand over bodies of strangers to the overseers of the poor in the town where the view is made, for burial, and to provide payment of fees in all cases by the County Treasury.

On motion of MEDICAL EXAMINER MEAD, the action of Medical Examiner Draper was approved.

MEDICAL EXAMINER PINKHAM read a paper entitled,

#### AN ANOMALOUS ARRANGEMENT OF THE VEINS OF THE NECK.

The usual site of the external jugular vein was occupied by a very large vessel which freely communicated with the internal jugular, and could be traced above to the jugular foramen, and below to the subclavian vein. The arrangement obtained on both sides of the neck. The subject had died from section of these anomalous vessels by a comparatively superficial cut.

Medical Examiner Pinkham also read a paper on, A CASE OF POISONING BY OIL OF CHECKERBERRY, WITH AUTOPSY.

A fluid-ounce of the oil was taken to produce abor-

tion. The essayist reported several other cases where toxic or lethal doses had been taken.

MEDICAL EXAMINER FISH spoke of the administration of the oil of checkerberry in rheumatic affections, and had given a fluid drachm or more in twenty-four hours without toxic symptoms.

DR. HURD reported a case of

#### RECOVERY FROM THE INGESTION OF HALF A PINT OF THE ESSENCE OF CHECKERBERRY.

MEDICAL EXAMINER DRAPER said that all essential oils were similar in their poisonous action, and reported a case of death from two fluid-ounces of oil of cedar, the fatal effect ensuing in about an hour.

ASSOCIATE MEMBER DAVENPORT stated that oil of birch is nearly pure methyl-salicylate, and does not contain gaultherylene as oil of checkerberry does. The heaviness of oil of birch is the cause of its adulteration with chloroform.

MEDICAL EXAMINER WINSOR made some remarks on the Lexington murder and mutilation case, mentioning evidence to show that the subject had died rapidly from hemorrhage and undoubtedly from one wound.

On recommendation of the Standing Committee, Arthur Lord, Esq., of Plymouth, was unanimously elected an associate member.

#### NEW YORK NEUROLOGICAL SOCIETY.<sup>1</sup>

DR. E. C. SEGUIN read a paper entitled

#### A CONTRIBUTION TO THE PATHOLOGY OF THE CEREBELLUM.

A detailed account of one case was given, and specimens, gross and microscopic, illustrating its pathological anatomy, were shown. Three other cases of cerebellar disease were briefly presented, as card specimens, with their anatomical demonstrations. The following is a summary of the first case: Male patient, forty-five years old at time of death; a retired officer of the United States Navy. Eighteen years before death, illness began with headache (not strictly occipital) and one or more seizures of an epileptiform or apoplectiform character. These were followed by impaired vision, and more or less continuous headache (fronto-occipital). Later appeared nystagmus and typical cerebellar titubation; slight slowness of speech. There was no distinct paralysis, true ataxia, anesthesia, vertigo, or mental impairment. During several years, from 1877 to 1883 or 1884, the only symptoms were slight frontal headache, defective vision, partial atrophy of both optic nerves, nystagmus of varying form, slight slowness and indistinctness of speech, increased patellar reflex, and titubation.

In February, 1885, an epileptiform seizure left behind it partial left hemiplegia, without contracture and anesthesia. Death on 22d of April, 1885, preceded by a set of distinctly bulbar symptoms; increased dysarthria, dysphagia, salivation, polyuria; also increasing stupor.

*Lesions.* Cyst of cerebellum, destroying the caudo-ventral part of the middle lobe (not involving frontal third of the vermis superior), penetrating into the right lateral lobe as far as the nucleus dentatus, not destroying it, and probably exerting only slight pressure upon the floor of the fourth ventricle. There

<sup>1</sup> Concluded from page 248.

were also found (1) a small, hemorrhagic focus, two millimeters in diameter, in the ventral half of the pons on the right side, in the midst of the pyramidal fasciculi. This explained the left hemiplegia, and from it, caudad, could be traced a complete descending degeneration of the right pyramidal tract into its subdivisions in the spinal cord. (2) Very extensive arteritis obliterans of the encephalic vessels, causing numerous (mostly symmetrical) foci of softening in the cerebral hemispheres. The only system-degeneration which could be traced to the loss of substance in the cerebellum was a moderate reduction in the size of the opposite (left) olive, and partial atrophy of the right restiform body.

The author called attention to several conclusions to be drawn from a study of these four cases:

(1) As to diagnosis: Tumors of the cerebellum produce very variable symptoms; but one symptom, namely, cerebellar titubation, is, as claimed by Nothnagel in 1876 or 1877, pathognomonic of a destructive lesion in the middle lobe of the cerebellum, more especially its caudo-ventral masses. In Dr. Seguin's cases, optic neuritis or atrophy had not failed, which was in marked contrast to his experience with tumors of the cerebral hemispheres, which do not usually cause lesion of the optic nerves (1:5 or 1:4). Vomiting was a frequent symptom; occipital headache and rigidity of muscles of the back of the neck were less frequent, but very valuable symptoms.

(2) As to therapeutics: Three of the patients had obtained repeated relief from serious symptoms—paroxysms of headache, vomiting, and epileptiform attacks—by the use of iodide of potassium, in doses of from thirty to sixty grains, three times a day.

(3) As to prognosis: Two of the patients did not die of their cerebellar disease (both cysts), but of complications. Case 1 of diffused arteritis obliterans, and consequent softening in various parts of the brain (including impaired nutrition of the bulbar nuclei); the other case, No. 2, of an acute tubercular meningitis. Consequently, we may hope, in a few cases, to cause or to witness an arrest of the cerebellar disease. The disorder in voluntary movements, and the already-developed lesions of the optic nerves, are, of course, irremediable.

#### DISCUSSION ON DR. SEGUIN'S PAPER.

DR. BRADNER spoke by invitation: He had been the attendant in the case of the child to which Dr. Seguin had referred. He had not prescribed the washing-out. It had been done by a prominent physician of the place. He had done it a number of times during three weeks, but had then refused, believing that the child had brain disease of some form. He saw the patient first in November. The vomiting was always in the morning. There was no pain connected with it then, although a frontal headache had developed during the last few months. The treatment prescribed by Dr. Seguin had been the iodide of potash, fifteen grains t. i. d., increasing five grains daily, until one hundred grains were taken at a dose. The course had been interrupted by several attacks of acute gastritis, but the child had had those attacks previously. They did not appear to depend upon the medication. The eyesight has been perfect; the child could detect the smallest point made by a lead-pencil or needle. While using the iodide his headache had improved, as had some other symptoms, but he retained his old-man's gait.

DR. SEGUIN remarked that, though seeing well, the child had typical choked disk.

DR. BRADNER added that, since seeing Dr. Seguin, he had obtained a history of injury in the case. Two years ago, and just before the commencement of his illness, he had, while trying to skate, fallen, and received a severe blow on the back of his head. One result of this injury had been abiding terror at the sight of a body of water or ice.

DR. SHAW had shown a child at the American Neurological Association in 1878, on account of a peculiar ataxic gait, like that of locomotor ataxia. The later symptoms had pointed to a tumor of the cerebellum.

DR. PUTNAM JACOBI referred to the recent collection of cases by Bernhardt. All cases published previous to 1884 had been collected by Nothnagel. Dr. Seguin's cases tended to confirm Nothnagel's laws. There were many resemblances between the symptoms of cerebellar tumor and those of tumor in other parts of the brain. The peculiar violence of the headache and the choked disk found in most cases of cerebellar disease might, she thought, be due to the increased pressure of a tumor confined by the tentorium. This element had not been commented upon, and she would like Dr. Seguin's opinion upon it.

Another point referred to the fact that the laws formulated by Nothnagel recognize the possibility of complete latency of the tumor, no symptoms at all being present when but one lobe of the cerebellum is affected; such symptoms appearing only when the tumor encroaches upon the central lobe. In one of Dr. Seguin's cases, the tumor only occupied the lateral lobe. Of course, an indirect affection of the central lobe might be present even in such a case.

DR. LESZINSKY referred to a case to which he was called in consultation by Dr. Alexander. The boy had the typical gait of spastic paraplegia; any attempt to stand caused spastic contractures in the limbs. The ankle clonus was present, and the knee-jerk was exaggerated. There were no cerebral symptoms; the fundus was normal in both eyes. The father and mother were both alcoholic and unworthy people. Finally the child became unable to walk, but there were still no cerebral signs, no vomiting. Two months before death the fundus was still normal. Later tremor developed, and paralysis of the abductors, of the fifth, and of the third nerves. Total blindness occurred. The nurse, a graduate of Bellevue, was positive that the child could see nothing. It died in a convulsion. Unfortunately, the body was immediately frozen, and the specimen was unfit for sections. The tumor was found occupying one side of the cerebellum. The spinal cord was not fit for examination. There was a well-developed meningitis, and the paralysis was accounted for by considerable exudation about the cerebral nerves. One peculiarity had been a subnormal temperature during one stage of the case.

DR. STARR had had occasion some time ago to make a collection of cortical lesions from American literature. He had at the same time made a collection of cases of cerebellar disease from the same sources. As the data obtained but corroborated Nothnagel's results, he never published them. But Dr. Seguin having remarked upon the value of corroborative evidence he would briefly refer to them now. From 1860 to 1884, 160 cases of cerebellar disease were reported in American literature. In only 40 of these

were the symptoms and the autopsies described with sufficient accuracy to warrant conclusions. These 40 the speaker had quite thoroughly analyzed. In four there were no symptoms; in one of these there was congenital atrophy of the cerebellum, in two abscess, and in one a large cyst. Of the remaining 36 presenting symptoms there was headache in 36, incoördination in 25, vertigo in 20, vomiting in 18, blindness in 14, dim vision in 6, diplopia or strabismus in 7, deafness in 7, facial spasm or paresis in 4, hemiplegia in 9, general paralysis in 4, mental symptoms in 8, stupid 7, mania 7, convulsions in 7, sexual desire increased in 2. Males 23, females 17. Ages between one and twenty years, 11 cases; between twenty and forty years, 16 cases; between forty and sixty years 9, cases; over sixty years, 1 case; age not stated in 3.

In two of the eleven cases in which incoördination did not occur the lesion probably involved the middle lobe. In cases where incoördination occurred various parts of the cerebellum were involved. But the probability was that the middle lobe was affected in the majority. There were only two instances of increased sexual desire. Bernhardt had found but one instance in ninety cases of cerebellar tumor, and Nothnagel but two cases. The speaker thought that it might be thrown out as a symptom of cerebellar disease, and regarded as one of accidental occurrence. The escape from vertigo in Dr. Seguin's case was explained perhaps by the recent discoveries in the anatomy of the course of the acoustic nerve. This nerve served for the sense of hearing and the sense of space. The center for hearing is in the pons. Edinger finds the center for equilibrium in the cerebellum to which acoustic fibres pass by way of the middle peduncle. From this center the central tract probably passes onward to the superior peduncle. Dr. Seguin says that the superior peduncle escaped in his case. It is therefore natural that vertigo should not have occurred.

The tendency to rotation was an interesting feature in these cases. There was a tendency to fall or turn forward in two cases; the lesion was in both a tumor in the vermis, in the anterior part. There was a tendency to fall to the right in two cases, in one there being a tumor in the left middle peduncle, and in the other an abscess in the same part. There was a tendency to fall to the left in two cases, in one there being an abscess in the right middle peduncle, and in the other a tumor in the left middle peduncle. A patient of Nothnagel, whom the speaker had seen in Vienna, when getting up in bed had always a tendency to turn to the right side. Nothnagel considered this due to vertigo. It was only present when the patient was erect. The patient felt as though about to fall to the left side, and hence turned to the right. This case had a tubercle of the left middle peduncle of the cerebellum. Nothnagel considered this symptom only produced by affection of the middle peduncle. In the two cases in the table where the tendency was to turn to the right there was disease of the left middle peduncle: while in the two in which the tendency was to the left, in one the right peduncle and in the other the left peduncle was affected. No rule can, therefore, as yet be laid down as to the cause of this symptom.

DR. ENGLISH had had charge of the case which formed the subject of Dr. Seguin's paper, and he congratulated the Society upon the progress which had been recently made in the diagnosis and treatment of

cerebellar disease. Early in 1878 Dr. Seguin had written him a letter, accurately diagnosing this case as seen on autopsy.

DR. SEGUIN closed the discussion. He was not surprised to learn of the little boy's fall, as he was a firm believer in the traumatic origin of these conditions. It was very difficult to obtain a history of fall. He could not give an opinion upon the question propounded by Dr. Putnam Jacobi. In regard to ascribing the vertigo to the acoustic nerve, he was not yet certain that the acoustic nerve had cerebellar origin. He thought it would be difficult to trace fibres through the lateral peduncle of the cerebellum, the vermis, and the anterior peduncle.

He said Dr. Starr had probably made a mistake when he referred to Nothnagel connecting rotation with disease of the middle peduncle. Middle vermis he had probably meant to say.

DR. STARR accepted the correction.

### Recent Literature.

*On Aphasia: being a Contribution to the subject of the Dissolution of Speech from Cerebral Disease.* By JAMES ROSS, M.D., LL.D. 8vo. pp. 128. London: J. & A. Churchill. 1887.

This little monograph is substantially a reprint of a series of papers that appeared in the Medical Chronicle, and is a very convenient work. The author gives first the report of ten cases illustrating the different forms of aphasia, most of which occurred in his own practice. These are followed by a very good résumé of our present knowledge as to the morbid anatomy of the affection, and the rest of the book is devoted to the morbid physiology of the disturbances of speech. He divides aphasia into a motor and sensory form. Motor aphasia is held to be a genuine motor paralysis, and is further subdivided into aphemia, agraphia, and amimia. Sensory aphasia, in like manner, is considered a true paralysis of sensation, and is subdivided into the aphasia of recollection, psychical blindness, and psychical deafness; psychical blindness including the word-blindness of Kussmaul and the soul-blindness of Munk. Beside these "disturbances of the apperceptive faculties" in sensory aphasia, the author considers that there are disturbances of the expressive faculties dependent upon the impairment of sensation, and these he classifies as paraphasia, paraphrapia, paralexia, paramimia, and apraxia. A good account of the theories of Kussmaul, Charcot, Lichtheim and Broadbent are given, with the various diagrams which these writers have used to illustrate their theories. The author, after advancing his theory that a motor or sensory paralysis is the bases of aphasia; attacks with considerable force Broadbent's theory of "idea" and "perceptive" centres. Furthermore the author, agreeing with Hughlings-Jackson's views as to evolution and dissolution in nervous disease, claims that nouns are the latest acquisitions in speech, and are therefore the most highly organized portion of it; therefore, when the faculty of speech is diseased, this most complex acquirement is the first to be affected, and the loss of nouns is due to this fact rather than to disease of any "naming" centre as Broadbent thinks. The book aids in making this difficult subject clear, and is an important contribution to our knowledge.

THE EXTRA-ASYLUM DEPENDENT INSANE.

II. THE INSANE IN ALMSHOUSES.

It is a sharp contrast to the report of the condition of the patients referred to editorially in our last issue, is that of a large number of the 684 dependent insane who live in almshouses. The first complete visitation of the Massachusetts almshouses was made in 1884. At no time have they undergone a full inspection, with reference to the number and condition of the insane inmates, by medical visitors conversant with the requirements of the insane. Occasionally, of late years, the State Board has authorized visitation by medical specialists in insanity for this purpose. The result has been, as a careful reading even of the condensed accounts published by the Board will show, to reveal a deplorable amount of neglect and wrong treatment, due largely to ignorance by most keepers of almshouses and by local authorities of the widely different care and management required, as a rule, by their sane and insane charges. Nor has it been the medical visitor alone who has recognized this wretched state of affairs. In an account of the visitation of 130 almshouses, in several counties, by Mrs. Sarah M. Brown, which appears in the last report of the Board, we read that: "In many cases, the insane are simply kept on the premises; but, with the limited accommodations, they are improperly cared for. The towns, on the score of economy, attempt to do in this direction work which, on the whole, is poorly done." Again: "Quite a number of those visited by me were greatly infested with vermin."

The dirty and disorderly state of poorhouses in many of the towns, in regard to which specific statements are made, is simply disgraceful. An expert examination in the almshouse in Fall River caused quite an acrimonious controversy in that city, partly political, of course, but, as a result of which, the superintendence has been changed twice, and still a third time this month, although leaving the main requirement unfilled, namely, a new almshouse, in place of the present defective buildings.

We find, also, that occasional acute cases of insanity, instead of receiving legal commitment and asylum treatment in the early and curable stages of the disorder, have, by reason of the mild nature of the attack, and for the sake of saving expense to the towns, been confined in almshouses from the first. The intermixture of the sane and insane, male and female inmates, has been found to be not properly guarded against in not a few of the poorhouses. In respect to the following points: selection of cases; facts as to sickness and death of the insane; the amount of room, matters of cleanliness and hygiene; amount of restraint and seclusion; number and kind of "cages" and "cells"; the kind and amount of diet; the state of the bedding, clothing, warmth, bathing appliances, water-supply, etc.—unfavorable observations have been repeatedly made. These criticisms, let us emphasize, do not necessarily apply to certain of the almshouses of the larger cities, in some of which the care of the insane leaves little to be desired.

The recent endeavors of the State Board to remedy these evils appear to be well directed, and it is unfortunate that the work was not undertaken long since. The recent legislation in this direction, especially that compelling the removal of unsuitable cases from almshouses, and the yearly visitations now being made by the direction of the Board, are indications of its appreciation of the necessity of supervision, and its desire to ameliorate the lot of these unfortunates.

Whether the building be new or old; whether there be separate wards or other special quarters provided for the insane of one or of several towns, their proper care undoubtedly will, in great measure, depend on whether or not a conscientious and efficient keeper falls to their lot. Their supervision, like that of all other extra-asylum insane of this class, should be undertaken by competent medical men, practised in matters of lunacy, who shall be properly paid by the State to make regular and thorough inspection. In default of such means, the only humane step is, we believe, to gradually commit patients now in almshouses to their proper asylums. They differ in no respect, it should be remembered, from a large number already in asylums, who have the benefit of medical supervision.

In the present overcrowded state of these institutions this would be impracticable, although we doubt, should this course be followed, if the treatment of curable cases in the asylums would be so far hampered as to offset by any means the good to come from delivering a number of insane patients from squalor and neglect. At all events, this transfer will no longer be looked upon as unwise when the project of providing for the over-accumulation of insane in our asylums, which is advocated by most superintendents, is put into operation. We refer to the erection, near each asylum, of small, inexpensive buildings for the accommodation of the chronic insane, these additions being made to keep pace with the gradual increase in the population of the main establishment. By this

means, economy, ease of administration, nicer classification, and constant medical care would be ensured; and we should hear little of the poorhouse lunatics, whose pitiable lot should be, we think, the strongest incentive for hastening the adoption of this desirable arrangement.

We cannot leave this subject without calling the attention of physicians in our various towns to the fact that their communities are but little alive to the needs of these victims of confirmed mental disease; and that it is in their power to encourage inquiry into, and to aid in rectifying, abuse and neglect in this quarter. Appeals to the State authorities, such as are frequent in matters of public health, cannot be made by the patient, and are often not made by others, as local interests are not thought to be especially involved.

#### STUNNING AND BURNING FROM ELECTRIC-WIRES.

As an incident in the development of the use of electricity for mechanical purposes, a class of injuries has arisen which present certain peculiarities. "Line-men" and "electric-light trimmers" are the ones most frequently injured; and in the pursuit of their vocations, as in every other dangerous occupation, there develops a certain carelessness, which, at times, proves fatal.

As the extensive use of electricity is of comparatively recent date, only a few fatal injuries of this description have been published. The remarkable instantaneous death of a workman at the Health-Exhibit in London, and a similar death of a sailor on the Russian Imperial yacht "Livadia," led Sheild and Delépine to carefully note the post-mortem appearances in a case that came under their observation, which they have recorded.<sup>1</sup>

They found that the blood remained fluid, and the heart was empty. They believe that it is quite possible to recognize an electric burn, not alone from its gross appearance, but also from certain peculiar microscopical appearances that exist in the blistered integument. The human body is, fortunately, a poor conductor of electricity; and it has been said by certain electricians, that a wire (in circuit) transmitting enough electricity to light fifteen lamps may be handled with impunity, if the circuit is not broken. Occasionally, however, a "lamp-trimmer" brushes against the wire with a wet rubber coat, or touches it with damp hands, thus breaking the circuit, and receiving a severe shock and burn. Three cases of this character occurred in Boston last autumn, where men received an electric-shock in the above manner. They were rendered unconscious, fell to the ground, and sustained, in addition to the bruising from the fall, a severe shock and local burns.

The burns were peculiar in that the tissues were completely destroyed, the surrounding parts ana-

thetized, and that, at first, there was no local congestion of the surrounding skin; the reparative process was very slow and tedious.

The period of unconsciousness varied with the severity of the shock, which, in two of the cases, was recovered from in a few days.

Prof. George Buchanan<sup>2</sup> reports the case of a laborer, who was stunned and burned while working in the vicinity of a brush-light. The victim was engaged in handling a crane. By the wire of the light coming in contact with a chain attached to the crane, he was brought into the circuit. He was instantly "doubled up," his hands spasmodically grasped the chain, and in this position he was held for four minutes, until the lamp and chain were disconnected. The amount of shock was slight, but a full hour elapsed before consciousness returned; he then complained of a sensation of heat in the abdomen, and slight dimness of vision. There was a slight vesication on the hands, and at the point on the sole of the foot from which the current passed into the ground, a charred surface, two inches square, remained. It is certainly remarkable that so powerful a current could pass through the foot without causing more injury in its passage.

The treatment of these cases is essentially that adopted for severe nervous shocks, the burns being treated as their intensity may demand.

#### CALOMEL AS A DIURETIC.

A WRITER in the *Practitioner* has recently called attention to the diuretic properties of calomel. It has long been known that the addition of calomel to certain diuretics, as squills and digitalis, enhances the action of those drugs.

The researches of Jendrassick are exceedingly interesting in this connection. It appears that the diuretic action of calomel is not immediate, but manifests itself ordinarily the second, third, or fourth day, generally reaching its maximum the second day, and then declining. The amount of diuresis depends on two factors: the dose of calomel employed, and the abundance of the dropsical effusion existing at the time of administration of the medicament. In Jendrassick's first experiments, the dose of calomel was four grains, three or four times a day; but the diuretic effect is naturally proportional to the quantity of calomel absorbed. The best results are obtained when the first symptoms of mercurial poisoning show themselves: metallic taste, pyalism, mild stomatitis. If the dose of calomel exceeds a certain limit it becomes purgative, and is carried off in the stools.

Jendrassick found that when once diuresis was induced by calomel, it lasted a long time, often not ceasing till the dropsical swellings had entirely disappeared; nor were further doses of the mercurial needed to keep up the effect. Calomel was found to

<sup>1</sup> Brit. Med. Jour., March 14, 1885.

<sup>2</sup> Lancet, February 13, 1886.

be especially useful in the dropsies of heart disease, with a sound state of the kidneys; in these cases, it proved itself a better diuretic, even, than digitalis.

The conclusions of Jendrassick have recently been confirmed by Collins in the *Medical Chronicle*, who has found two or three five-grain doses of calomel an incomparable diuretic in dropsical effusions.

#### MEDICAL NOTES.

—The Forty-Ninth Congress appropriated \$10,000 toward the approaching International Medical Congress to be held in Washington next September. It is provided that the amount appropriated is to be expended under such regulations as the Secretary of the Treasury may prescribe, also that no part of the appropriation shall go toward paying the personal expenses of any delegate, and no money shall be expended except upon vouchers to be approved by the Secretary of the Interior. The sum asked for by the Committee of the Congress was \$50,000.

—The *Pall Mall Gazette* has, in its endeavors after a new sensation, hit upon a *plébiscite*, in which the public are invited to record a vote on the "best doctor" in general; the "best woman's doctor"; the "best dentist"; the "best surgeon"; the "best-managed hospital," etc. "The usual prizes of £2 and £1 will be given to the two competitors whose coupons agree most nearly with the opinions of the majority." Meantime, our English brethren of the profession are very highly and properly incensed at the impertinence of the whole scheme.

—The National Dental Hospital of England, and the College of Surgeons of Edinburgh, have both decided to admit women for the study of dentistry. None have yet presented themselves, although the *Dental Register*, issued by the Medical Council, contains the names of twenty-two women, of whom sixteen practice in England, two in Scotland, and four in colonies. These women were all registered as being in practice before the passage of the "Dentist's Act." Thus it is seen that women are not rushing into the profession with the celerity which might be expected from the throwing open of the doors.

—The *London Medical Record* refers to two cases of rumination in man, reported by Dr. Johaussen in the *Norsk Magazin for Lægevidenskaben*, November, 1886. Case I, was a man, aged twenty-five, unmarried. At sixteen years old he had sudden pains in the chest and diplopia, and remained ill three weeks; he had also headache, noises in the ears, and gastric pains. On recovery, he remarked that food returned into his mouth, especially when after a meal he worked in a forward attitude. The regurgitations became more frequent, and after a few years occurred after every meal. Remastication occurred with the same satisfaction as at first. All kinds of food returned, solids and liquids. The rumination begins within a few minutes to half an hour after a meal, and lasts an hour or two.

The regurgitation is involuntary, and the patient has never tried to prevent it. He has vomited only twice in his life, and then only after too much alcohol. During the last six months he has noticed a change in his condition—the food regurgitated has been accompanied by a bitter substance of disagreeable taste—and he is thinner. Case 2, was a young medical man in fair health.

—The United States Consul, at Buenos Ayres, in his dispatch to the United States Treasury Department, dated January 7, 1887, says: "Cholera still exists in this city, but it makes but little progress in assuming an epidemic form. The average number of cases per day since my last dispatch (December 6th), has not exceeded 22. The greatest number of reported cases in one day occurred on the 30th ultimo, when the number reached 57, since which time it has steadily declined, and on yesterday the number was only 11 in the city, with its population of 400,000 souls." He encloses a clipping from the Buenos Ayres *Standard*, from which it is learned that during the months of November and December there were 871 cases of cholera, and 474 deaths from that disease. The consul also states that "the disease has scarcely made its appearance except in closely packed tenement-houses (conventillos of the lower classes and in the suburbs, which are without pipe and hydrant water. In the interior of the Argentine Republic, however, the disease has assumed the proportions of an epidemic. In Rosario, during the last month, the daily number of cases averaged 60 to 100, while about 70 per cent. were fatal. In Mendoza the development of the disease has been most remarkable, and the population of that city of 20,000 has been almost decimated; and in the country districts the disease was equally fatal. In Tucuman the number of cases has on some days been as high as 500, of which about one-half proved fatal. Indeed, the panic at one time was so great that it was not possible to obtain the requisite assistance to bury the dead. In nearly all the other interior cities the disease has been very virulent and fatal, but, not confining itself to centres of population, it has ravaged entire provinces, and farmers (estancieros) and camp men have in great numbers succumbed to it. I am happy to say that with medical assistance, disinfectants, medicines, and a large supply of good nurses, the disease seems to have greatly abated during the last two weeks, and the hope is entertained that it will soon have run its course."

#### BOSTON.

—The death of Hon. Zenas M. Crane, the veteran paper manufacturer of Dalton, Mass., which occurred last week, is said to have revealed in him the anonymous contributor of \$10,000, which sum was received by the Massachusetts Eye and Ear Infirmary, five years ago in response to an appeal for subscriptions.

—The Directors of the West End Nursery and Infant's Hospital, 37 Blossom Street, urgently appeal for further aid to enable them to continue the work of

the institution. It is only through a still further response to the needs of the work, of at least \$3,000, that the thirty babies now under the shelter of the nursery can be cared for during the coming year, and aid extended to the other helpless infants who may demand the care of charity.

— A shocking accident occurred on the morning of March 14th, whereby a local train on the "Dedham Branch" of the Boston and Providence Railroad was precipitated through a broken bridge, a distance of twenty-five or thirty feet, into the road-way below, at a point in West Roxbury. Of nine cars, composing the train, five thus fell through between the abutments, where they were piled upon each other. About twenty-five persons were killed outright, and between eighty and one hundred injured, many of them very severely. Both the morgues in Boston were filled with the bodies of the dead, some of which were crushed so as to prevent identification, except by the dress and other personal effects. One woman had her head completely severed from the body, and another had the head cleft downwards, so that one side of the skull and face were removed. In these more extensive mutilations, comparatively little blood was lost. One of the cars took fire from the stove, but the flames were extinguished promptly, so that this so common source of danger and horror was removed from the case. The wounded were many of them taken at once to their homes, and five or six patients were admitted to the City Hospital and the Massachusetts General, each; while others were dressed in the out-patient departments, and sent to their homes.

#### NEW YORK.

— The New York State Academy of Veterinary Science and Comparative Pathology held a meeting March 4th, at which there was adopted a set of resolutions for presentation to the Legislature, in which it was stated that, while during the past year, 37,330 deaths occurred in New York, 16,000 of this number were in children under five years of age, and that the Academy believed that many of these deaths were caused by diseased meat and adulterated milk. There were only four milk inspectors and one meat inspector for the whole city, and the Academy regard the establishment of public abattoirs, when cattle could be examined before and after being slaughtered, and also of depots for the examination of milk. Furthermore, it was asked that the number of inspectors should be increased, and that every candidate applying for the position of inspector should first be examined by a commission consisting of one member from the Board of Health, another from the Microscopical Society, and the third from the State Academy of Veterinary Science. An amendment was added to the effect that every veterinary surgeon should be required by law to report to the Board of Health all cases of contagious disease that came under his notice among animals. At this meeting Dr. J. P. Gerrish read a paper

on tuberculosis in man and in cattle, and a general discussion of the subject followed.

— Governor Hill has at last, after nine months' delay, signed an order approving of the removal of General Shaler, President of the City Board of Health, by Mayor Grace; the General in the meanwhile having continued to hold his position at the head of the Department. It is said that he will adopt legal measures for re-installment in office, but it seems hardly likely that they will be successful, as the feeling is strong in the community that a man who has practically been twice convicted of bribery, although the jury did not agree at either trial, is not a fit person to hold one of the most important among the municipal offices.

— The Mayor is said to have appointed Mr. James C. Bayles, editor of *The Iron Age*, and an expert sanitary engineer of high repute, President of the Board of Health, in the place of General Shaler.

— The Crosby bill now before the Legislature providing for a single head for the New York Board of Health, has been modified, in accordance with the wishes of Mayor Hewitt, so as to establish a three-headed commission, the President of which is to be the executive officer of the Board, and to be solely responsible for the discharge of all duties of an executive nature. The other two commissioners are to be clothed with judicial and legislative powers, and to act in conjunction with the President in these functions.

— Dr. Lucien Damainville has been appointed a police surgeon to fill the vacancy caused by the death of Dr. Francis M. Purroy.

— The annual commencement of the Medical Department of the University of the City of New York, was held at the Academy of Music, March 8th, when degrees were conferred upon one hundred and fifty-one graduates. Gilmore's band furnished the music, and the address to the class was made by the Rev. John R. Paxton, D.D.

— The twenty-first annual commencement of the New York College of Dentistry was held at Chickering Hall, March 9th. The graduates numbered fifty-one, and were addressed by W. A. Parrington, Esq., Counsel for the Medical Societies of the State and County of New York.

— Dr. W. S. Searle, family physician of the late Henry Ward Beecher, has made a statement of his case in which he says that prior to the attack of apoplexy, Mr. Beecher was a remarkably sound man for his age. The only complaints to which he had ever been subject were tonsillitis, so-called bilious attacks, and hay-fever. So far as could be known, his only organic trouble was a very limited amount of chronic nephritis. Like all corpulent men, he labored somewhat under shortness of breath, and, without having made an examination, Dr. Searle feared that he might perhaps have some fatty degeneration of the

heart. But the powerful and persistent action of this organ during his late illness proved this apprehension to be unfounded, while no man living had more capacious or better innervated lungs than his. The seat of the apoplexy was apparently in the right hemisphere, involving the motor tract, and the rupture was no doubt one of a small vessel, as indicated by the gradual and progressive character of the paralysis which resulted. By Saturday morning the effusion had become sufficiently extensive to produce almost total loss of motion in the left arm, as well as to seriously impair the control of the corresponding lower extremity. Sensation, in these parts, however, was still intact; but the hæmorrhage went on, the paralysis became more and more marked, until it finally became entire in respect of both motion and sensation. Thus, on Sunday morning it was discovered that sensation was completely abolished in the whole left side of the face, and even in the conjunctiva. Subsequently the disease did not deviate from the usual course observed, and death resulted from the gradual failure of the vital powers.

— Dr. William Young has just got a verdict in the Superior Court of \$3,538.88, which is the full amount of the bill, with interest, which he claimed against the estate of the late Frederick P. James, a wealthy banker, for professional services rendered from December, 1881, to May, 1884, when Mr. James died. For fifteen years before his death, he was a paralytic, and had various complicating affections of the different organs. The defence claimed that the bill was too high, and that Dr. Young had profited in certain stock speculations through Mr. James's knowledge of the market; but it was proved that the doctor had paid him commissions as he would have done to any other broker.

— The sum of \$53,050 mentioned last week in connection with the Hospital Saturday and Sunday Collection was the entire amount collected, and the necessary expenses had to be deducted from this: Mt. Sinai Hospital received the largest share of any, \$5,727; St. Luke's the next, \$4,486; The Hospital for Ruptured and Crippled next, \$4,121; the Presbyterian next, \$3,625; and the German next, \$3,555. The other hospitals received amounts varying from \$1,929 (St. Mary's Free Hospital for Sick Children), to \$354, (the Home for Convalescents). The different amounts were assigned at a recent meeting of the Distributing Committee, which consists of Mayor Hewett, Morris H. Jesup, Jesse Seligman, Cornelius Vanderbilt and ex-Mayor Edward Cooper.

— The seventh anniversary of the Home for Convalescents was celebrated in Dr. Crosby's church on the 9th of March, when addresses were made by the Rev. Drs. Crosby and Ormiston and others. This is a most worthy charity, the object of which is to give temporary shelter and comfort to those who have been discharged from the hospitals not wholly recovered from the effects of illness, and it is the only insti-

tution of the kind in the city. It was opened in June, 1880, with six beds, and since that time it has received 775 inmates, for many of whom it has obtained employment on their full recovery. It now has a building in East 118th Street, provided with twenty beds.

### Miscellany.

#### A DEATH FROM CHLOROFORM IN TRENTON, NEW JERSEY.

A DEATH from the administration of chloroform is reported from Trenton, N. J., and the *Daily American* of Trenton, contains a communication from a resident physician in which the unfortunate occurrence serves as the text for a reiteration of sound doctrines as to the relative safety and desirability of ether and chloroform.

#### CARBOLIC ACID IN THE TREATMENT OF VOMITING, AND PAINFUL DYSPESIA.

THE well-known anæsthetic and analgesic effects of carbolic acid were first utilized in the treatment of vomiting by Dr. Edward Garraway,<sup>1</sup> of England. He found drop doses of carbolic acid in some suitable vehicle to allay as by magic hysterical vomiting and the vomiting of pregnancy. Drs. Dixon and Beran afterwards employed the same remedy in the same dose for the relief of some forms of painful dyspepsia; the latter associated with it a certain proportion of the *acetum opii* (English black drops).

Recently, Pacholier<sup>2</sup> has essayed the combination recommended by Dr. Beran, in obstinate cases of chlorotic vomiting, in the vomiting of pregnancy, in gastralgia from dilatation of the stomach, and from anæmic, nervous causes; and he reports remarkable success from this palliative treatment of these affections. His formula is as follows:

Pure deliquescent Carbolic Acid,	1 part.
English Black Drops,	3 parts.
Mix. Dose — four drops in a little sweetened water three times a day, a few minutes after meals.	

#### POISONING FROM A VAGINAL INJECTION OF SUBLIMATE.

THE *Therapeutic Gazette* publishes the following instructive case, which originally appeared in the *Centralblatt für Gynäkologie*, by Fleischmann, of Prague. A perfectly healthy primipara, aged seventeen, exhibited no symptoms of kidney disease, or of any other complication of pregnancy. To disinfect the vagina before labor, two douches of 1 to 2,000 solution of sublimate were given, one before and one after examination by a midwife. It was noticed that a small amount of bloody mucus was expelled from the vagina after the douches. In a few hours abdominal pain, diarrhœa and a rise of temperature occurred, all the symptoms and lesions of mercurial poisoning developed, nephritis, salivation and continued diarrhœa, and, after giving birth to a living child, the patient died in coma on the ninth day after the douches were

<sup>1</sup> British Medical Journal, March 13th, 1869.

<sup>2</sup> Bulletin Gen. de Thérapeutique, February 15th, 1887.

given. The pathological anatomical diagnosis made at the autopsy was "corrosive sublimate intoxication, acute nephritis, dysentery, stomatitis and pharyngitis in the stage of ulceration, parenchymatous degeneration of heart and liver, lobar and lobular pneumonia bilateral, acute cystitis."

#### INSANITY AS A MEASURE OF BRAIN-FAILURE.

DR. T. S. CLOUSTON in reading his annual report to the corporation of the Royal Edinburgh Asylum for the Insane recently, said that so far as society was concerned, the chief significance of the amount of definite mental disease that occurs every year in a community, consists in the fact that it is the most measurable and ascertainable of all the brain failures. It was the one sort of mental wreckage that was so absolute as to admit of tabulation and classification. It was not necessarily different in kind from many of the mental causes of business failure, of moral incompetence, of social disaster, or of many kinds of non-success in life. It was merely different in degree. The failures of energy and power of work at critical times, the paralysis of effort in study or action, the "unaccountable" changes of purpose, or of emotional condition that have such far-reaching effects in life, might all arise from brain-failures allied to insanity, but neither society nor science as yet had any means of estimating the number or the causes of such catclysms. Instability of brain took many forms. The present humane methods of healing mental diseases might at first have the same general effect as modern improved sanitation and care for the diseased, the weak, and the young of delicate constitutions, who would formerly have been allowed to die, and so be done with. At present, the weakly in mind and body are kept alive by every means, and sedulously cared for. There was no doubt that the evolutionary law of the survival of the fittest was thus opposed. If they had no indication from science that weak and unstable brains could become strong and stable in succeeding generations under favorable conditions of life, and that brains with one or two weak points might have in other directions elements of strength of the greatest service to humanity, but for such indications a great part of what modern philanthropy and medicine were doing for the insane might not be thought of unquestionable benefit to mankind.

#### THE INEQUALITY OF THE PUPILS IN VARIOUS DISEASES.

THE *Lancet* (January 15) quotes from *Vrach* a number of observations made by Dr. Pasternatski, who has been working in Professor Chudnovski's clinic in St. Petersburg, on the inequality of the pupils in various diseases, in pursuance of a suggestion made by his chief in a work on the methods of examining medical patients, published in 1883, in which he expressed an opinion that careful examination of the pupils would lead to interesting results. Dr. Pasternatski examined a number of methods which have been proposed, but did not find any of them suitable for his purpose, and ultimately, a much simpler plan, suggested by M. Follin, was adopted. This consists in

bringing a catheter-gauge card close to the eye, and comparing the size of the pupil with the apertures in the card. By this means, the size of the pupil, in millimeters, can be ascertained with a degree of accuracy sufficient for the purpose. It is important to make the observations in the shade, for the difference, when there is any, between the diameters of the pupils increases as the light is diminished. The best method of conducting the examination is to close the eye which is not being observed, for this causes a slight increase in the diameter of the pupil of the latter, as was indeed remarked by Hippocrates. It was found, for example, in a case in which this was tested, that when both eyes (being in the shade) were fixed on an object at a distance, the diameter of the right pupil was  $5\frac{1}{2}$  mm., and that of the left 6 mm.; when, however, the eye not under examination was covered up, the diameters increased to 6 mm. and  $6\frac{3}{8}$  mm., respectively. As to the diseases in which inequality of pupils has been observed, Dr. Pasternatski quotes a number of cases mentioned by continental physicians: also one of aneurism shown by Professor Gardiner to the Edinburgh Medical Society, as well as two reported by Professor Finlayson in the *Lancet* of January 3d, 1885, in both of which aneurisms were found at the necropsy. His own observations gave the percentage of cases in which inequality was found in various diseases as follows: Croupous pneumonia 85, heart diseases and aortic aneurisms 61, pleurisy 52, chronic catarrhal pneumonia 38, acute articular rheumatism 25, catarrh of the respiratory passages 25, scurvy 16, typhus 16, recurrent typhus (relapsing fever) 15, abdominal typhus (enteric fever) 13. Inequality of pupils was also found in half the cases of catarrhal and hepatic jaundice and renal colic. The largest percentage occurred in croupous pneumonia, and study of the cases showed that the position and stage of development of the disease has a remarkable effect upon the pupils. At the very commencement, the pupil on the same side as the affected lung is, as a rule, larger than the other. The difference generally increases with the lung inflammation, reaching its height on the third, fourth, or fifth day; before the crisis the difference decreases, sometimes even disappearing. Afterwards, during the stage of resolution, a difference is again manifest, the pupil on the affected side being now contracted. Not only do the pupils in pneumonia differ in size, but also in sensibility to light. Speaking generally, the author's observations lead him to believe that inequality of pupils is most frequently met with in those internal diseases which not only affect the system generally, but which, like pneumonia, pleurisy, and hepatic and renal colic, are definitely localized as well. It is also very usual in heart diseases and aneurism, but comparatively rare in curvy and infectious diseases, such as typhus, and when it does occur in these, it is generally consequent on some complication.

#### Correspondence.

##### REMOVAL OF FOREIGN BODIES IN THE CESOPHAGUS, ETC.

SMITHSBURG, MD., February 12, 1887.

MR. EDITOR.—In a recent JOURNAL I read an account of some cases of foreign bodies in the cesophagus and also

of their treatment. These cases brought to mind some experiences of my own, the relation of which may be of some value to the profession.

In one case a lady allowed a very crooked pin to be caught in the upper part of the pipe. I was called at night, and after learning the situation, I procured an elastic switch ten inches long, secured a small piece of sponge to one extremity by notching the twig and then wrapping the sponge where it enveloped the notched end of the twig with strong cord. Then I sewed the sponge full of loops of hair from my horse's tail. This improvised instrument I passed down to the pin, continually rotating it, both in introducing and withdrawing. The pin was caught in the loops.

In another case, a piece of bone, which we call spare-rib, was accidentally swallowed, because the patient having no teeth bolted his food. The bone lodged in the lower part of the esophagus. At first he could not swallow water but later other soft substances passed down. He came to me about the third day, complaining of pain, worse when swallowing, and of inability to swallow food. As it was butchering time I readily procured some raw fat pork. This I cut into small bits, having a piece of skin attached to each. The whole when together making a bulk as large as a hulled walnut. Each piece of pork was attached to a piece of cord exactly fourteen inches long. These he swallowed one after the other. After they were all down I brought the ends of the cord strings evenly together so that I might know that the meat was massed below. Then I made traction which provoking an effort at disgorgement, I speedily recovered my pork but the bone was not with it. But as he could and did swallow

mouthful of dry bread soon after, I concluded that the dislodged bone had dropped into the stomach, while the pork held the esophagus open.

Is it not possible to dislodge formidable foreign bodies from the esophagus by swallowing bits of compressed sponge with the attached cords carefully numbered? The expansion that would follow their wetting would so stretch the pipe as to loosen the foreign body and permit it to drop into the stomach. An India-rubber bladder attached to a tube of the same or of metal could be passed down and be blown out with air or with water from a sufficiently elevated reservoir.

I have a case of Bright's disease, and the patient has had an occasional attack, something like epilepsy, and some difficulty of vision in which he could only see distinctly the lower half of an object. He is not dropsical. One evening he came into his room and lay down. After apparently sleeping for an hour he was discovered to have one of his "spells" (insensibility without spasm) and I was sent for. When I arrived, half an hour later, he had partially recovered consciousness and was rubbing the soles of his feet energetically. When any one else attempted it he would exclaim that they hurt him. Thinking there might be muscular spasm I tried grasping the foot tightly but it hurt him so severely that I had to desist. After a while, however, he became easier and I left. At my next visit on the following morning I found two large blisters occupying the sole upon each heel, located alike and almost alike in size, shape and extent. I should like to have the cause of their occurrence explained.

Very truly yours,

E. TRACY BISHOP, M.D.

Deaths reported 2,567, under five years of age 984; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas and fevers) 357, acute lung diseases 408, consumption 346, diphtheria and croup 166, measles 59, diarrheal diseases 41, typhoid fever 40, scarlet fever 28, malarial fevers 15, cerebro-spinal meningitis 14, whooping-cough 10, erysipelas 10, puerperal fever seven, small-pox (New York five, Brooklyn two), seven. From typhoid fever, Philadelphia 15, New York five, Pittsburgh four, Lowell three, Brooklyn, Boston, New Orleans, District of Columbia and Somerville two each, Baltimore, Fall River and Newton one each. From scarlet fever, New York 16, Philadelphia, Brooklyn and Boston three each, Newport, Taunton and Milwaukee one each. From malarial fever, New York, six, New Orleans four, Brooklyn two, Philadelphia, Baltimore, and District of Columbia, one each. From cerebro-spinal meningitis, New York, five, Philadelphia, and Fitchburg two each, Baltimore, Pittsburgh and Springfield one each. From whooping-cough, New York three, Brooklyn two, Philadelphia, Boston, Baltimore, District of Columbia and Pittsburgh one each. From erysipelas, New York, Baltimore and District of Columbia two each, Brooklyn, Providence, Gloucester and Northampton one each. From purpura fever, Brooklyn and Milwaukee two each, Portland, Providence, and Springfield one each.

Cases reported in Boston: measles 51, diphtheria 51, scarlet fever 25, and typhoid fever five. In Milwaukee, scarlet fever 29 and diphtheria 14, Newport, 10 cases of measles.

In the 22 cities and greater towns of Massachusetts, with a population of 1,177,418 (population of the State 1,941,465) the total death-rate for the week was 18.55 against 20.68 and 20.52 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,245,000, for the week ending February 19th, the death-rate was 21.1. Deaths reported 3,736; infants under one year of age 874; whooping-cough 125, measles 107, scarlet fever 47, diarrhoea 36, diphtheria 32, fever 23, small-pox (Newcastle) one.

The death-rates ranged from 17.2 in Derby to 29.6 in Preston; Birmingham 23.3; Blackburn 22.3; Bradford 20.2; Hull 18.6; Leeds 20.7; Liverpool 25.8; London 19.3; Manchester 28.6; Newcastle-on-Tyne 24.3; Nottingham 18.4; Oldham 22.2; Sheffield 24.2; Sunderland 22.1.

In Edinburgh 23.8; Glasgow 27.1; Dublin 35.3.

The meteorological record for the week ending March 5, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending	Barometer.	Thermometer.		Relative Humidity.			Direction of Wind.		Velocity of Wind.		State of Weather.		Rainfall.

GUITERAS, JOHN, passed assistant surgeon. Granted leave of absence for twenty-one days, February 28, 1887.

PETTUS, W. J., assistant surgeon. To proceed to Charleston, S. C., for temporary duty, February 28, 1887.

#### OBITUARY.

##### CHARLES B. UNDERHILL, M.D.

Dr. C. B. Underhill, of Salda, Col., died of consumption at his mother's residence on Cutter Street, Somerville, Mass., in February. He was a graduate of Harvard College, in the class of 1877 and of the Medical School in 1881. He served eighteen months as Medical House-Officer in the Boston City Hospital. Close application undermined a not very strong constitution, and he went to Colorado for his health. The climate prolonged his life, but could not cure the disease, and he returned home to die, after spending five years in the practice of his profession. He was thirty-one years of age and unmarried. As a physician he was successful, and was beloved by all who knew him.

SUBSEQUENT HISTORY OF A PATIENT WITH AN ABDOMINAL TUMOR DIAGNOSTICATED AS FLOATING SPLEEN IN 1877.<sup>1</sup>

BY F. C. SHATTUCK, M.D.,

Visiting Physician Massachusetts General Hospital, etc.

In June, 1878, I had the honor of reading at the annual meeting of the Massachusetts Medical Society, a paper on "Floating Spleen," a paper which was published in the transactions of the Society for that year, and also in the *Boston Medical and Surgical Journal*. I was led to choose this subject by encountering a case which I believed to be of that nature. Under a lively sense of the fact that it is well for us to report our mistakes and bad cases as well as our triumphs or good cases, I will first very briefly recall the leading facts in the patient's previous history, and then lay before you in more detail his subsequent history, with an account of the autopsy. In July, 1877, I saw for the first time, a well-built young man of eighteen, a baker by trade. A fortnight before he went to bed in usual health, was awakened in the night by severe pain in the left hypochondrium, and then discovered that he had a tumor in his abdomen. After careful and repeated examination I decided that the tumor was an enlarged, displaced, and movable spleen, an opinion concurred in by a professional friend in whose knowledge and skill I had and have the greatest confidence, this gentleman not knowing my opinion until his own was formed and expressed. The possibility that the tumor was a kidney was entertained and rejected. The patient returned immediately to his work, at which I found him busy nearly a year later, when I looked him up and examined him again while preparing my paper.

In July, 1886, never having seen the patient in the interval, I found him in my ward at the Massachusetts General Hospital. He said that four or five years ago he had had an attack of acute pain in the left side with stoppage of water and subsequently hæmaturia. This recurred several times, but there had been no attack for a year and a half. June 17th, he strained himself, as he thought, lifting a barrel of flour, and had been unable to work since, except for a week about a fortnight after his alleged injury. He reported himself as being perfectly well except for dull pain in the lumbar region and left side. The nutrition was very fair. The abdominal tumor showed no marked change since I saw him eight years before, but the axillary, inguinal and cervical glands were somewhat enlarged, and the liver seemed to be uniformly enlarged, the lower edges extending to the umbilicus and across the median line. No nodules could be felt. The urine contained a slight trace of albumen and a few casts; the quantity and specific gravity were normal. That there was something more in the case than there had been was evident enough, but I was unable to reach any diagnosis. He declined in strength, but August 10th, it was found necessary to discharge him to make way for cases of typhoid fever which were coming in rapidly, and at the same time our beds were diminished in number by changes in some of the wards.

August 16th, he was admitted into the City Hospi-

<sup>1</sup> Read before the Boston Society for Medical Observation, February 7, 1887.

tal, the records of which as bearing on his case are most kindly placed at my disposal by Dr. A. L. Mason. He still complained of pain in the back, and of increasing weakness. The legs had become somewhat "numb," and his control over them was imperfect. For the last few days the micturition, previously normal, had been "delayed;" no fever, urine as before. The patella reflexes were increased and ankle clonus was marked; on the outer aspect of the right thigh there was a circumscribed area of diminished sensibility. In the left back, about three inches below the angle of the scapula, was a smooth rounded tumor two inches in diameter, not movable, but adherent to the skin, tense, elastic, fluctuating. (?)

August 21st. Paraplegia was now almost complete and the reflexes were less marked. At times there was retention of urine, the bowels were constipated, there was moderate fever.

August 31st. He passed per urethram about a pint of clear blood. Numerous clots formed in the bladder and were voided with difficulty by the aid of a large catheter. Expressed himself as "perfectly comfortable." The hæmaturia continued several days; there was incontinence of urine and feces. The hepatic swelling increased, and the edge of the organ was now to be felt two inches below the level of the umbilicus, and in the flank just above the crest of the ilium. The other tumor was unchanged.

September 11th. Several bed-sores had developed over the lower back. He was losing flesh and strength rapidly, though he had a fair appetite and was still "perfectly comfortable."

October 9th. He died, having steadily failed without the appearance of any new symptoms.

AUTOPSY, twenty-one hours after death, by Dr. Gannett.

*Body.* Medium size, fairly well developed and nourished. Much emaciated. Rigor mortis present. Anterior abdominal wall green.

*Head.* In posterior part left of the parietal bone about two cm. from median line was a circular loss of substance about two cm. in diameter. This was filled with a soft grayish mass, growing in the diploe and projecting both internally and externally about three mm. The brain showed nothing remarkable beyond pallor.

*Spinal Column, etc.* Spinal canal, opposite last dorsal and first lumbar vertebra, was about one-half normal size, the lumen being diminished by a growth from the vertebra into the canal. Spinal cord, corresponding to this point, was softened, more opaque and yellow; all distinction between gray and white matter being lost.

Section through last two dorsal and first two lumbar vertebra showed that the marrow was almost entirely replaced by a soft, red, and almost gelatinous new growth.

In left vertebral groove, corresponding to these vertebra, was an ovoid mass, rather larger though not quite so wide as the palm of the hand, and about twice as thick, connecting with the above described vertebral growth.

*Ribs.* Similar nodules of size of large plums on third and fifth ribs in front on right side, and on fifth right rib behind, close to vertebral column, all growing from the medulla of the bone.

*Heart and lungs* were not remarkable.

The *spleen* was normal in size and weight; it lay

between the ninth and eleventh ribs, with its anterior border two inches behind the costo-articular line. The gastro-splenic omentum was short; when strong traction was made downward and forward, the spleen could be moved two inches in front of the costo-articular line, and below the eighth cartilage.

The *left kidney* was represented by a three-lobed mass, about the size of the two closed fists, placed one upon the other. The peritoneum covered not only the anterior surface, but also the posterior surface, like a meso-colon, making the kidney freely movable, so that it could be brought as far as the median line.

On section, the upper portion was found to be made up of a two-lobed, solid mass of a grayish, firm substance, in which yellow and more opaque streaks and specks could be seen. The lower half was a cavity, the size of the fist, with irregular, shreddy walls, having grayish, somewhat translucent and rather friable masses hanging from its inner surface. Outside of this, laterally, was a thin layer of renal substance, in which the distinction between cortex and pyramids could still be made out, though with difficulty, this tissue being quite pale.

The pelvis of the right kidney was deeply injected and thickened; it contained considerable calcareous material. The kidney showed several vertical purulent lines.

The *bladder* showed thickening on pigmentation of the mucous membrane.

The *right ureter* had an injected mucous membrane.

The *liver* measured transversely, twelve; vertically, thirteen; antero-posteriorly four inches; weighing a little less than ten pounds. It was thickly studded with gray and red nodules, varying in size from that of a pea to that of a man's fist.

**PATHOLOGICAL DIAGNOSIS.** *Cancer* of skull, vertebrae, ribs, kidney, liver. *Myelitis* from pressure. *Cystitis*. *Pyelo-nephritis*.

#### SUMMARY.

A muscular and well-nourished man of twenty-seven has, for at least nine years, had an abdominal tumor, thought to be a movable spleen. He has worked steadily at a laborious trade, and had no symptoms which could possibly be referred to his tumor, except several transitory attacks of hæmaturia. Immediately after lifting a barrel of flour, he is disabled by pain in the back, soon followed by progressive loss of strength, and later, of flesh; enlargement of the liver and superficial lymphatic glands; an elastic tumor below the left scapula; fever, acute myelitis, hæmaturia, and death from exhaustion within less than four months from the time when he was in full activity and apparent health.

The autopsy showed cancer of the skull, vertebrae, ribs, kidney, and liver; myelitis from pressure, cystitis, pyelo-nephritis. The spleen was perfectly normal in size and position.

My original diagnosis was, therefore, entirely wrong. The abdominal tumor was the left kidney, not the spleen. It will be noted that, at the autopsy, Dr. Gannett—to whom I wish to express my great obligation for his careful report of the case—found the peritoneum stretched, and investing the whole kidney, like a meso-colon.

Movable or floating kidney is much more common in women than in men: out of ninety cases collected by Ebstein, eighty-two were females. In congenital

malpositions of the kidney, it is usually the left which is anomalous, the organ being fixed, but lying lower down than the normal seat. It is thought that movable conditions of the kidney are acquired, and in more than two-thirds of these it is the right kidney which becomes displaced.

There are two questions suggested by a consideration of the case, above reported, to neither of which can a definite answer be given: In the first place, how long was the kidney out of place before I first saw the patient, in 1877? It is, of course, impossible that such elongation of the peritoneum came on suddenly. Tight-lacing was certainly not a factor in causing the dislocation. The occupation of the patient was a laborious one, but I do not know how long he had followed it before the tumor was discovered. As he was only eighteen at the time, it could not have been very long. The second question is: When did this cancerous growth begin? I took no measurement of the tumor when I first saw it, but it is my impression that it was larger than a normal kidney. I considered it to be an enlarged, as well as a floating spleen. It may be that, from twisting of the ureter, the pelvis of the kidney became early somewhat dilated. But to what were the attacks of hæmaturia, recurring between five and one and a half years before his death, due? May they be attributable to acute and temporary strangulation or stoppage of the ureter? When the patient once began to go down hill he went very rapidly; but he considered himself in perfect health up to the time of his supposed strain from lifting the barrel of flour.

#### REPORT ON THE PROGRESS OF SURGERY.<sup>1</sup>

BY H. L. BURRELL, M.D., AND H. W. CUSHING, M.D.

#### COLOTOMY.

SONNENBURG<sup>18</sup> has relieved patients suffering from carcinoma of the rectum by operating in the following manner. The abdominal wall was incised in the linea alba, the peritoneal cavity opened, and the colon divided transversely above the point of disease. The lower end was then closed by suture, and dropped back into the abdominal cavity. The superior end was brought forward and fastened into the median incision, below the umbilicus. The advantages claimed for this method are that the surgeon has an opportunity to examine the intestine in regard to the exact nature of the neoplasm, its situation or size, and to change the plan of operation to a more advantageous one, if necessary. The intestine is opened at a known point, and as low as possible, so that solid dejections are voided from the artificial anus. The contraction of the recti muscles serves to constrict the artificial opening, and act as a substitute for a sphincter. The anus, in this position, is more conveniently situated for the patient than in the Amussat or Littré operation. Also, the irritation, pain, ulceration, decomposing discharges, and other complications arising from access of feces to the intestinal pouch, situated between the seat of stenosis and the artificial opening, is avoided. In case the rectum is wholly occluded, suturing the lower end of the divided intestine into the wound in the linea alba is recommended. This

<sup>1</sup> Concluded from page 258.

<sup>18</sup> Berl. Klin. Wochenschr., December 6, 1886.

gives an opportunity to keep this portion clear from collecting mucus or discharges.

#### HEPATIC SURGERY.

At the last annual meeting of the British Medical Association,<sup>19</sup> this subject was considered by Dr. Harley, Mr. Thornton, Mr. Willett, Mr. Marsh, and Mr. Tait. Although the contributions are fragmentary in that they deal with a new field of surgery, yet there is much of interest in their papers. Dr. Harley reported a "Case of Hepatitis, with Dropsy, in which Hepatic Phlebotomy was performed."<sup>20</sup> The operative procedure consisted of piercing "the upper part of the liver from right to left with an eight-inch trocar, approximating, in size, a No. 2 to 3 English catheter," the hope being that, during its transverse penetration, that one or more veins or arteries might be wounded. Twenty ounces of hepatic blood were removed, with the most salutary effects, the patient recovering completely from the dropsy and hepatitis. Dr. Harley simply seals the abdominal puncture with sticking-plaster, and bandages the abdomen tightly, with the idea of bringing the wound in the liver's capsule into contact with the abdominal parietes.

Mr. Thornton records three cases of hepatic surgery; and says that he "believes that all diseases of the liver which are within the surgeon's reach may be, and should be, treated on the same lines that would guide us in the treatment of similar diseases in other situations, and with every prospect of equally satisfactory results."

Mr. Willett reports a case of complete obstruction of the common duct, where cholecystotomy was performed, with marked improvement. The question of whether external drainage of the gall-bladder or establishing an entero-biliary fistula is the better surgery, is discussed by Mr. Willett, and he considers the latter operation indicated. "There seem to be but two sites where naturally-formed entero-biliary fistulae occur. In nearly thirty cases collected by Murchison, in about two-thirds the fistulous communication was located in the duodenum, and one-third in the colon.

Mr. Willett elects the colon, but discusses fully the advantages of a duodeno-biliary fistula. Mr. Marsh simply records a case of abscess of the liver.

Mr. Lawson Tait reported seven cases of exploratory incision, with one death; thirteen cases of hepaticotomy, with no deaths; and thirty cases of cholecystotomy, with no deaths.

#### PENETRATING GUN-SHOT WOUND OF THE ABDOMEN, INVOLVING THE LIVER; INTRA-PERITONEAL HÆMORRHAGE; LAPAROTOMY.

J. W. Heddens<sup>21</sup> reports a case, where, believing that there was a hæmorrhage into the abdominal cavity, he performed laparotomy. The course of the bullet was traced to the liver; a piece of the patient's vest was found in the peritoneal cavity and removed. The wound was dressed antiseptically, and a prompt recovery ensued.

#### SURGICAL INTERVENTION IN CERTAIN CASES OF BILIARY CALCULUS.

T. Thiriar,<sup>22</sup> in an admirable paper on cholecystec-

tomy, states that Prof. Wehenkel, of Brussels, in six thousand autopsies failed to find any gall-stone in the liver; hence the gall-bladder is almost a necessity in their formation; consequently for the radical cure of this affection it is necessary to remove this viscus. Three cases are related (Langenbuch one, Thiriar two) all of which recovered. Seven cases, five by Langenbuch, two by Thiriar, are mentioned, in none of which cases was death referable to the operation itself. Thiriar claims that cholecystectomy is the rational operation, and considers that the indication for operating is a frequent recurrence of severe biliary colic which has resisted medical treatment. His method of operating is as follows: Great care is taken about the temperature of the room, baths and the antiseptic preparation of the patient. Previous to the operations one to two gms. of laudanum, and two to four gms. of chloral are given by enema. The spray is used and full antiseptic precautions. The incision follows the right rectus abdominis, the muscular fibres of which are cut transversely three finger's breadth below the false ribs. After adhesions with the colon are broken down, the gall-bladder is seen. The cystic duct is then isolated, ligatured with silk in two places and divided. The margins of the opening are sewed together with fine sublimated silk. The gall-bladder is removed and the abdominal wound closed.

#### GALL-STONE ILEUS.

An exhaustive paper by Wising,<sup>23</sup> a review of which has recently been published,<sup>24</sup> gives many interesting and valuable data on this subject. Wising reached his conclusions from 51 cases, 41 of which were collected by Leichtenstern from among 1,541 cases of ileus. Usually it is caused only by exceedingly large calculi; but can occur when a smaller calculus becomes impacted in a faecal mass, or when there is a previous intestinal contraction. This class of stones usually enter the intestine through a fistula resulting from a perforating ulcerating process. It may escape into the duodenum, colon, or stomach. The seat of obstruction in 33 cases occurred 12 times in the jejunum and 21 times in the ileum, especially in the lower half.

As to clinical symptoms in cases of perforation from the gall-bladder to the intestine severe suffering is by no means invariably present. Only in one-third of the cases does severe pain in the hepatic region occur. Icterus is not a regular accompaniment of perforation (8 cases in 51). Symptoms of ileus appear soon after the stone has entered the intestine, but a diagnosis of ileus from other causes is not possible. Pain may be very variable, sometimes disseminated, sometimes more localized. Tympanites and character of vomitus depend on the seat of obstruction: when low down faecal vomiting is a late symptom. A tumor is rarely felt (5 cases in 51). Of the 51 cases 38 ended fatally. Since a brief *résumé* of such an article can by no means do justice to it, a perusal of the above-mentioned review or its translation<sup>25</sup> is recommended.

#### SPLENECTOMY.

Mr. J. Knowsley Thornton<sup>26</sup> has reported two cases of splenectomy, in which details are fully recorded. One of the cases was successful, and ap-

pended is an analysis of all previously-recorded cases. Ceci A.<sup>27</sup> has also successfully removed an hypertrophied displaced spleen in a young subject.

THE RADICAL CURE OF OBLIQUE INGUINAL HERNIA BY INTERNAL ABDOMINAL PERITONEAL PAD, AND THE RESTORATION OF THE VALVED FORM OF THE INGUINAL CANAL.

Forty-seven cases of the above operation are reported by William Macewen,<sup>28</sup> with no deaths. Fourteen of the forty-seven cases were subjected to operation for radical cure after the relief of strangulated inguinal hernia; three afterwards wore a truss, as a precautionary measure. Of the thirty-three operated upon directly for a radical cure, only one wore a truss, and this was from force of habit.

Nine cases of femoral hernie were similarly treated, after the relief of strangulation. None of these patients require a truss.

A short description of the operation may be given, but the details are best obtained from the original paper, which has numerous cuts, illustrating the steps of the operation. The hernia (inguinal) having been reduced, an incision is made over the external abdominal ring, the sac isolated from the cord and canal in which it rests, and the peritoneum is separated by the tip of the finger for about half an inch about the internal abdominal ring; then a stitch is passed through the distal extremity of the sac, and the ends of the threads are passed through the folds of the sac, transfixing it proximally, so that, when pulled upon, the threads pull up the sac, like a curtain. The free end of this stitch, threaded on a hernia-needle, after traversing the canal, is made to penetrate the anterior abdominal wall about an inch above the internal ring, the skin being pulled upward, so as to allow the point of the needle to penetrate the muscles, but not the skin. This stitch is then tied, drawing the sac into a series of folds, which are placed just inside the internal abdominal ring, thus forming a pad of peritoneum over the internal abdominal opening.

The operation is completed by the introduction of stitches, which are passed from the conjoined tendon to the aponeurotic structures of the transversalis, internal and external oblique muscles, restoring, in this way, the valve-like form of the canal. Strict antiseptic precautions should be observed.

THE IMMEDIATE CLOSURE AND RAPID CURE OF FISTULA IN ANO.

Stephen Smith<sup>29</sup> gives the particulars of his method as follows: After the patient is anesthetized, and the parts to be subjected to operation made antiseptic, a sponge wrung out in bichloride solution is passed up the rectum, above the fistula. The fistula and its branches are freely opened, the pyogenic membrane is thoroughly removed with scissors or scalpel, and all hemorrhage stopped. Then an assistant, with his index finger introduced well up the rectum, extrudes the whole track of the fistula. Sutures are next so applied that the deep parts are brought accurately together, and the margins of the mucous membrane everted. This is accomplished by taking "a large-sized carbolized silk or chromic-acid gut ligature, and attaching a needle having a slightly-curved point to

each end. One needle is now passed just above the highest point of the incision, and from a fourth to half an inch from the margin of the wound, and the thread is drawn through to its centre. The needles are then passed in opposite directions, at intervals of about half an inch, in the same manner as the saddler takes his double-stitch when two pieces of leather are held in a vice and united. If the fistula is simple, and there is no abscess-cavity, the stitches are continued to the external extremity of the incision, making a continuous suture on each side of the wound."

They are now tightened sufficiently to evert the margins of the mucous membrane; and the ends of the ligature are held by an assistant, who draws out the whole fistulous track, while a nicely-applied continuous suture unites the mucous membrane. A drainage-tube is inserted into the external extremity of the wound. This is all done aseptically, and iodoform-gauze pads are applied. The sponge is withdrawn from the rectum, and a suppository of morphia is inserted. The diet should be milk, and no defecation allowed for from four to six days.

"The principles which should be borne in mind in the operation are. (1) Complete removal of the lining membrane of the fistula, and of the abscess-cavity which may exist. (2) Accurate and permanent adjustment of the opposing surfaces. (3) Thorough antiseptic treatment of the wound."

THE TREATMENT OF AORTIC ANEURISMS BY THE INTRODUCTION OF WIRE AND GALVANISM.

Dr. Cayley's case, on which Mr. Hulke<sup>30</sup> operated, introducing forty feet of steel wire into the sac of an aneurism, with the result of solidifying the tumor, gave rise to an interesting discussion, bringing up the following points: (1) That the introduction of foreign substances is usually easy. (2) That, so far as experience goes, the proceeding appears to involve very little danger when it is carefully carried out.

Mr. Barwell<sup>31</sup> reports a case of an aneurism of the arch of the aorta, involving its lower aspect, treated by the introduction, through an ivory stylet, of ten feet of the finest steel wire. The end of the wire was connected with the positive pole of a battery; the negative pole being placed over the upper dorsal region, then a current of nine milliamperes was passed through the circuit for one hour and ten minutes. The pulsation was more distant, and the tumor was harder at the end of twelve hours. On the fourth day a new tumor formed, which soon ruptured, and the patient died.

## Hospital Practice.

### BOSTON CITY HOSPITAL.

#### TWO CASES OF COMPOUND, DEPRESSED FRACTURE OF THE SKULL.

REPORTED BY OLIVER H. BOWE, M.D., formerly House-Surgeon.

CASE I. DELAY AND NEGLECTED TREATMENT BEFORE ENTERING HOSPITAL; LATE OPERATION, SHOWING ABSCESS OF BRAIN; DEATH; AUTOPSY.

M. D., FIFTY-SEVEN years old, and a laborer, entered the hospital (service of Dr. E. H. Bradford) April 5th. His history was that, a week before entrance, a brick fell from a height of four stories, striking him on the forehead, knocking him down, and making a wound about two and one-half inches long. This wound was sewed up at once by a doctor. The wound seemed to heal readily, and the man felt all right until two days

before entrance, when he began to have pain in his head, and became very stupid and weak, and very sensitive to pressure about the wound.

Examination, at time of entrance, showed, on the left side of the forehead, about two inches above the eyebrow, a soft, fluctuating, and exceedingly tender area of the size of a half-dollar, not raised above the surrounding surface. Extending across this area was a semi-circular, linear cicatrix. This cicatrix was complete, except at its middle, where was seen a small opening, just admitting a probe, from which opening there exuded, on pressure, a drop of bloody pus. By dilating the opening and using pressure, about a drachm of pus escaped, and the probe detected an area of bare bone underneath, a part of which was depressed about three-sixteenths of an inch, the edge of the depressed portion coinciding with the cicatrix outside. The pupils were equal, and responded equally to light. Slight divergent strabismus in the left eye. Convergent strabismus at times. No hemiplegic symptoms found.

Patient is very stupid, scowling, and cross. Friends say he was somewhat so before the injury. He remained in the hospital, at this time, thirty days, stubbornly refusing to have any operation done for raising the depressed bone. His headache persisted, and his moods did not change. Free openings for discharge from the wound were maintained, and pus was washed out from time to time.

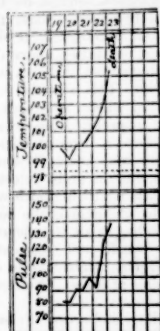

May 19th, eighteen days after leaving the Hospital, and fifty-one days after the receipt of the injury, the patient was brought in again, this time in an unconscious condition. The story was that, after leaving the hospital, his condition had remained unchanged until twelve hours before entrance, at which time he became suddenly unconscious, and his right side became paralyzed.

Examination showed the wound in about the same condition as on leaving the hospital. Patient is completely unconscious. Hemianesthesia and paralysis of motion of right side, but right arm and leg show considerable rigidity on passive motion. Facial paralysis on right side. Pupils unequal; both react, but the right slowly. Divergent strabismus; flush over upper part of body. Respiration 24; slightly stertorous in character. Pulse 72, irregular and soft.

Incisions were made to expose the seat of fracture. The bone was found depressed over an area the size of a silver half-dollar, and the edges of bone were carious at the line of fracture. The skull was trephined at the edge of the depressed portion, and some of the depressed bone removed. The dura was then opened, and an incision made into the brain substance, which resulted in the evacuation of about two ounces of bloody pus. The opening in the brain was then explored with the finger, which was passed in up to the second joint. A small cavity was felt, the walls of which seemed quite firm to the touch. The cavity was thoroughly washed out by irrigation, and a large drainage-tube inserted.

There was no appreciable change in the patient's condition immediately after the operation. The next day, sensation in right leg and arm returned to slight degree, but there was no motion. Prick of pin on right side caused quick motion of left side, which it did not do before the operation. The second day after the operation he seemed to understand what was said to him, and said "No" in answer to questions.

Muttered to himself. The next day he was wholly unconscious again; respiration was again stertorous. The fourth day after the operation, the temperature,

which had been gradually rising, shot suddenly up to 105.3°, and the pulse to 138.

Cyanosis became marked, and sensation was lost on the left side. The question of further operative measures was considered, but dismissed. The cavity was again syringed out, no pus being obtained. He died about an hour later.

At the autopsy, made by Dr. Gannett, a cavity, the size of a large common walnut, was found, directly communicating with the opening made by the trephine. The walls of the cavity were formed of brain substance, and were quite smooth and dry. Close to the cavity just described, was a second one in the brain substance, the size of a filbert, and filled with pus. The brain substance about both cavities was rather softer than usual, of a yellow color, with numerous minute red points. This change extended for a distance of about three centimeters into the brain substance.

#### CASE II. PROMPT TREATMENT: RECOVERY.

J. S. was struck on the head by a bolt on a large revolving pulley at an electric-light station. Two hours later he came to the hospital. At the anterior part of the top of his head, to the left of the median line, and on both sides of the coronal suture, were two wounds (see diagram), each about four inches long.

At the bottom of the anterior wound, the bone was comminuted and depressed over an area about  $2\frac{1}{2}$  inches long by  $\frac{3}{4}$  inch wide, the outer table being driven down below the level of the inner table. In the posterior wound, the skull was comminuted and depressed in a space about  $1\frac{1}{2}$  inches long by  $\frac{3}{4}$  inch wide, the outer table being depressed about one-fourth of an inch below the level of the surrounding bone. The man was entirely conscious, and showed no symptoms from the injury. He was a vigorous, healthy-looking man; said he had never been sick, and that he drank moderately. Pulse 60.

Ether was given, and Dr. Gay trephined the skull at the outer side of the anterior wound, and raised and removed all the fragments in the anterior depressed portion, the opening extending to the median line over the superior longitudinal sinus. The dura was exposed, and, so far as examined, did not appear to be lacerated. The posterior depressed portion was not touched. The whole was done antiseptically, and a dressing of iodoform gauze applied.

The man remained in the Hospital thirty-one days,

during which time the wounds steadily closed, until, at the time of his discharge, only two superficial, granulating surfaces, each of the size of a quarter-dollar, remained. There was no pus for the first two weeks after the operation; after that, a moderate amount from the granulations. Pulsation was visible in the anterior wound for about three weeks. During the whole time the man had no symptoms of any kind, and no pain, except immediately following the operation. The temperature, during the first two weeks, never rose above 99.2°; after the first two weeks it was normal. The pulse, for three days following the operation, was about 90. It then fell to about 60, where it remained till the man began to sit up, after which time it was about 75.

These two cases illustrate the difference in result between good and bad treatment.

In the case of M. D., although a depression of three-sixteenths of an inch existed, the wound was sewed up. It consequently healed, leaving the seat of mischief sealed over. Later on, the ignorant and stubborn patient refused proper treatment; and, as a result, the cerebral abscess, sudden unconsciousness, and death followed.

In the case of J. S., although the injury was apparently much more severe, he received appropriate treatment within three hours after the accident; free drainage was maintained, no symptoms occurred, and the man made a good recovery.

### Clinical Memorandum.

#### A CASE OF ABDOMINAL PREGNANCY.

BY ENOS H. BIGELOW, M.D., FRAMINGHAM.

JANUARY, 1887. C. A., American, thirty-three years, of rather slight frame and active habit, medium height, average weight about one hundred and fifteen pounds. Seven years ago she bore a child now living. Was married a second time in 1882. Since this last marriage she has suffered from occasional attacks of pain in the bowels, accompanied with difficulty of micturition and some vaginal discharge.

In June, 1886, not long after a menstrual period, she complained of severe pain in the abdomen, together with nausea and difficulty in urinating. She had however had, previously to this, similar, but less severe, attacks. An examination made at this time showed per vaginam the presence of old pelvic inflammation and adhesion, the uterus being immovably fixed posteriorly.

Through the summer and fall she had several attacks of severe pain, at first attributed entirely to the presence of leucorrhœa, with heat and tenderness about the uterus, indicating some peri-uterine inflammation, or endometritis; later, however, the presence of pregnancy being demonstrated, the pain was thought to be due to the enlargement of a uterus which was surrounded by inflammatory tissue, and more or less fixed thereby. In November, the placental souffle was very evident, and appeared close to the ear placed at the right groin. The abdomen was uniformly distended and sensitive to the touch, making palpation painful and unsatisfactory.

Some time in October it was remarked that the

movements of the fetus, which had been distinctly felt, ceased entirely. Late in November there was an offensive discharge from the vagina, and the woman's strength began to fail. Hectic fever, a low typhoid condition, sallowness, and other symptoms of blood-poisoning, developed slowly. Examined per vaginam the os and cervix were patulous, admitting the finger as far as the internal os. The uterus was so fixed and surrounded by inflammatory deposit as to make it impossible to define its outline or size.

December 8th. Dr. Z. B. Adams saw the woman in consultation, and suggested extra-uterine pregnancy as a possible explanation of her condition, and advised that she be etherized with a view to more accurate diagnosis.

December 14th, she was etherized and a more thorough exploration made. The uterus was found to be empty, and of about the normal size, and a diagnosis of extra-uterine, probably abdominal, pregnancy, was made.

The advisability of operation by abdominal section was carefully considered. The patient and friends were informed of her unfortunate condition, and an operation was offered but not strongly urged. The arguments in favor were faithfully presented, but, because of the difficulty anticipated in dealing with the placenta, no encouragement could be given that it would be successful in preventing a fatal termination, whereas on the other hand, the case could not be proved to be absolutely hopeless if left to nature. She declined operation.

The woman gradually sank and died of septic peritonitis, January 23, 1887.

Autopsy twenty-four hours after death. Emaciation extreme, abdomen greatly distended. Three gallons of chocolate-colored fluid in abdominal cavity. The peritoneum was necrosed and showed large patches of lymph. Stomach and bowels empty. Fetus perfectly formed, sixteen inches in length, was free in the cavity of the abdomen. The spine presented and the head lay under the right lobe of liver and in contact with it. The placenta was attached very firmly to the right peritoneal surface extending four inches above the crest of the ilium and occupying the pelvic cavity of that side. The right tube was thickened, distended with dark fluid, and involved in old adhesion. No rupture of either tube was discovered. The uterus was compressed and lay low in the pelvic cavity, posteriorly placed and against the rectum.

Difficulty of diagnosis. An hysterical woman; a uterus involved in adhesions resulting from previous pelvic inflammation, fixed and immovable, and revealing nothing to the touch of its form and size; and the presence of a general peritonitis with abdominal distension and tenderness, and fluid in the dependent parts. Under ether, however, it appeared that the womb was empty, and the presence of a tumor resembling a fetus together with a pretty clear history of pregnancy, made a correct diagnosis possible.

— *Life* remarks that in Boston they do not say stomach-ache, they call it "gastric neuralgia," but it gets there just the same.

— It is said that a favorite tannic medicine in use in the New York hospitals is named, for obvious reasons, the "Early Bird."

## Therapeutical Memorandum.

### THE VALUE OF THE BILE SALTS WHEN USED IN CONJUNCTION WITH INUNCTIONS OF COD LIVER OIL.

BY ROBERT AMORY HARR, M.D., (UNIV. OF PA.),  
Demonstrator of Experimental Therapeutics and Instructor in Physical Diagnosis in the University of Pennsylvania.

WITHIN the last few months I have had occasion to use cod liver oil by inunction several times when the stomach was not in a condition to bear its internal use, and while I have hitherto frequently prescribed this line of medication, I never fully realized the difficulties and the disagreeable conditions produced until such a line of treatment was introduced in my own family. In the first place the amount of rubbing necessary is a great objection to its use when the patient is very weak, or when the oil is being applied to a young child where the area is comparatively limited. Again, the amount of exposure during the inunction in the endeavor to protect the clothing is by no means slight, and if the greatest care is not exercised in regard to this, the invalid's clothes, which are necessarily stale enough, are made positively unbearable to both himself and friends. It occurred to me that as one of the functions of the bile salts was to aid the passage of fats through animal membrane, that perhaps they would act in the same manner when applied to the skin, and practical results have proved this theory to be true. The fact that cod liver oil inunctions are productive of good results is so well known, that any report of such cases is superfluous, and I shall therefore simply describe the method which I have used. In obtaining the salts I have simply gone through the process used commonly in a physiological laboratory, but it may not be out of place to briefly give the method here. To about 300 cc. of ox-gall is added nearly thrice that quantity of ordinary alcohol, and the flask shaken thoroughly. All the mucus is now precipitated and the supernatant fluid is filtered. To the filtrate is added a large excess of sulphuric ether and after a time a plaster-like mass forms at the bottom of the vessel, which slowly becomes crystalline. These crystals are now placed on a filter paper and washed with a mixture made up of ether and alcohol, equal parts. The filter paper is dried and the substances then seen are the taurocholate and glycocholate of soda. Having carefully removed these salts from the paper they are ready for use.

In my experiments I have found that a small pinch of this powder will aid very materially in the speed with which a teaspoonful of the oil is absorbed, and that the rapidity of absorption is in direct ratio with the quantity of bile salts used. Thus, if half a teaspoonful of the oil be placed on the thin skin of the inside of the thighs, and bile salts added to the oil on one side, both legs being rubbed equally hard, it will be found that the oil with the bile salts added disappears in nearly half the time that is required for the absorption of the pure oil. In addition to the increased rapidity of absorption it will be noticed that even after all the oil has been rubbed in on both legs, there still remains a strong odor of the oil and some greasiness on the limb rubbed with pure oil, while on the opposite limb the odor is greatly decreased, as is also the greasiness, which may indeed be entirely absent, proving that all the oil has passed from the surface.

Several repeated applications of bile salts and oil to the same spot within twenty-four hours, has failed to produce any sign of irritation of the cuticle. I think, therefore, that this use of the bile salts deserves more than a mere trial, and the avoidance of the odor and the hand-rubbing is certainly a strong point in its favor, aside from the increased quantity of the oil which is by this means absorbed.

At my suggestion, Messrs. Fairchild Bros. & Foster, of New York, the well-known manufacturers of digestive ferments, have undertaken the preparation of these bile salts, and any physician desiring to use them can obtain them from this firm.

### Reports of Societies.

#### PROCEEDINGS OF THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.

E. O. OTIS, M.D., SECRETARY, *pro tem.*

MEETING February 7, 1887.

DR. E. J. FORSTER, in the chair.

DR. M. H. RICHARDSON showed two specimens of stone in the bladder. The first illustrated the difficulty often met with in searching for stone. It was taken from the bladder of a man about sixty who had been catheterized daily for a year with a metallic instrument, and yet no suspicion of stone had been entertained by the attending physician. On careful examination a faint click had been detected at the Massachusetts General Hospital, by Dr. Richardson. Even then it was so doubtful that for some time the presence of a calculus had been doubted by other surgeons present. The stone was easily found and crushed with the lithotrite, and weighed twenty-one grains. The patient made a good recovery. The second case was that of a man who died of some lung trouble, probably phthisis, some months after an operation had been done by Dr. Richardson for the removal of a phosphatic stone from the bladder. There had been no difficulty in the operation and the patient seemed all right as far as the bladder symptoms went. An examination after death revealed the presence of a small stone which was encysted on the wall of the bladder so as to be almost wholly concealed. At the end of the operation the bladder seemed to be quite empty, and the water came into the evacuator perfectly clear. The failure to detect the very small presenting portion of the stone at the final introduction of the searcher was probably due to the almost complete covering up of the stone by the inflamed and swollen mucous membrane. It seemed to the speaker that this would have been a better case for suprapubic lithotomy than for crushing, had it been possible to know that there was an encysted stone. Such errors would be avoided if the supra-pubic operation were done in all doubtful cases.

DR. F. B. HARRINGTON presented the notes of a case of

OSTEO-SARCOMA OF THE LOWER JAW: OPERATION, and exhibited specimens of the tumor prepared by Dr. Whitney.

DR. RICHARDSON said that this was one of the largest and bloodiest operations he had ever seen. He inquired if there were not troublesome cicatricial con-

tractions from the loss of the mucous membrane, mentioning a case of his own in which this had occurred to such an extent that the mouth could be only slightly opened.

DR. HARRINGTON replied that in this respect he was more fortunate.

DR. F. C. SHATTUCK presented a paper upon

THE SUBSEQUENT HISTORY OF A PATIENT WITH AN ABDOMINAL TUMOR DIAGNOSTICATED AS FLOATING SPLEEN IN 1877.<sup>1</sup>

DR. RICHARDSON asked if there were any evidences of kidney disease given by the urine at the time of the original examination.

DR. SHATTUCK replied that he thought the urine was not examined; at least he had no record of it.

DR. HARRINGTON asked if the hamaturia might not have been due to the cancer rather than to the strangulation or stoppage of the ureter, as suggested.

DR. SHATTUCK replied that as the patient had several attacks of renal hamaturia during the four years, the question was as to the possible growth of the cancer all this time.

DR. GANNETT said he agreed with Dr. Harrington that the hamaturia was caused by the cancer which had existed all this time. He also presented a diagram showing the abnormal arrangement of the peritoneum about the kidney.

DR. SHATTUCK said that as he understood the matter, a kidney may become displaced and gradually elongate the peritoneum, thus becoming an acquired movable kidney in distinction from a congenital one, which lies lower than normal, but is fixed. This man's kidney was out of place and enlarged nine years before his death. Cancer of the kidney (in children at least) is of comparatively short duration.

DR. GANNETT said that acquired movable kidney happened in most cases in those who having been very fat lost much of their adipose tissue.

DR. SHATTUCK stated that movable kidney is most common on the right side in women and occurred frequently, irrespective of loss of fat about the kidney or elsewhere.

DR. RICHARDSON asked if the tumor at the time of death was any larger than at the first examination.

DR. SHATTUCK thought not, but at the last there was in addition the enlarged liver, lymphatic glands, etc.

DR. FORSTER said he had seen the case at a later period than Dr. Shattuck, and it seemed to him that the tumor increased after the man entered the hospital.

DR. CHANNING inquired how long Dr. Shattuck thought the kidney had been in the position and condition noted, and was answered that that could not be definitely told, undoubtedly for some time before the first examination.

DR. GANNETT inquired if Dr. Shattuck had made any note of the splenic percussion, and was answered that there was no dulness in the splenic region.

— FRANCISO MAGIN, an eminent Italian ophthalmologist, director of the anatomical school at Florence, and later professor of ophthalmology at Bologna, died at San Remo, February 2, 1887, aged 59.

<sup>1</sup> See page 273 of this number of the Journal.

## THE NEW YORK ACADEMY OF MEDICINE.

STATED meeting, February 17, 1887.

## ADDRESS BY THE PRESIDENT.

The President, DR. A. JACOBI, delivered an address, the object of which was to discountenance the various methods resorted to by certain members of the profession to advertise themselves in the newspapers and in other ways.

DR. C. L. DANA read a paper on

## SPASTIC ATAXIA, FUNCTIONAL AND ORGANIC, AND THE COMBINED SCLEROSES OF THE SPINAL CORD.

The object of the paper, he said, was to show a class of cases, not very rare, which correspond to some extent with ordinary progressive locomotor ataxia, but to a much more marked degree with spastic paraplegia. This affection it was important to recognize, both for prognosis and treatment. He had been able to collect forty-five cases of combined sclerosis, observed by various authorities, including two, the history of which, with the autopsies, were reported for the first time in the present paper; but all but sixteen of these he felt obliged to exclude, on account of various circumstances, which, he thought, prevented them from coming properly under the head of the class of cases of which he was treating: those so admirably described by Gowers, and designated by him as ataxic paraplegia. Dr. Dana had notes of seven cases, six of which occurred in males, and one in a female; and he related several of them in detail.

In describing the symptoms, he said that there was gradually-increasing weakness of the limbs, with some loss of power of coördination; but the lancinating pains of tabes were, as a rule, absent, while the knee-jerk was increased, instead of being lost, as in the latter affection. The "Argyll-Robinson" pupil was also seldom seen. As the disease advanced, the muscular power became more and more impaired, while the incoördination did not proportionally increase, but was over-shadowed by the increasing paralysis. The increased myotatic irritability continued, and stiffness and rigidity developed as its consequence. "Thus," as Dr. Gowers had so well described it, "the aspect of the patient comes to be that of spastic paraplegia: the feet drag as the patient walks, shake from clonus when he stops, and the legs are hauled forward with visible effort at each step." Sexual power was often lost early in the disease. The sphincters were frequently impaired, but the impairment rarely reached a considerable degree. There was, as a rule, no wasting of the muscles, and no change in their electrical excitability.

The pathological condition found, *post mortem*, by Dr. Dana, was chronic cervico-dorsal myelitis, affecting the lateral columns primarily, the gray matter secondarily. In a case, the drawings from which he exhibited, there were secondary degenerations in the lateral columns, and ascending and descending development of sclerosis in the columns of Goll. In addition, there was sclerosis of the crossed pyramidal tracts, most marked in the dorsal region, and sclerosis in the cerebellar tracts to a moderate extent. The sclerosis in the columns of Goll was most marked in the cervical region. According to Gowers, in all cases the spinal cord has presented sclerosis of both posterior and lateral columns; but the precise extent and degree of

the degeneration seem subject to considerable variations. As a general rule, he says the sclerosis of the posterior columns differs from that of tabes in two particulars: First, it is not more intense, and often is less intense, in the lumbar than in the dorsal region of the cord. Sometimes, indeed, in the middle and lower parts of the lumbar region, the posterior columns may be free from sclerosis, although it is considerable in the dorsal region, and at the junction of this with the lumbar enlargement. The second difference is that the sclerosis has rarely the special intensity in the root-zone of the postero-external column that characterizes the lesion of tabes.

The prognosis as to life, Dr. Dana went on to say, was better than in simple tabes dorsalis. The disease had little tendency to cause death; indeed, according to Gowers, the fatal cases had, for the most part, been untypical, and did not convey an accurate idea of the character of the disease. The chief danger to life was from the accidents common to all chronic spinal affections, and especially from kidney disease secondary to retention. So far as the prospect of recovery was concerned, the prognosis was unfavorable; and one case was on record, in which the affection had already lasted thirty years.

The treatment did not vary greatly from that of locomotor ataxia. Rest was a very important element, and electricity, both static and in the form of the faradic current, was useful. Orthopedic appliances to support the enfeebled limbs were often of great service. Anti-syphilitic treatment should always be thoroughly tried; and later, large doses of iodide of potassium were to be resorted to. In conclusion, Dr. Dana said that, while no name had as yet been found which properly described the disease clinically, he thought the designation, combined fascicular sclerosis, was applicable from a pathological point of view. (During the reading of the paper he exhibited a number of sections of the cord, photographs, and drawings illustrating the subject.)

DR. M. A. STARR said that he thought we still had to look for a thoroughly satisfactory name; and that the one proposed by Dr. Dana, combined fascicular sclerosis, ought not to be accepted, since the pathological changes met with after death showed that the affection was not entirely fascicular in character. The diagnosis between tabes and combined sclerosis, he remarked, was often very difficult; and, again, the occurrence of general paresis in connection with tabes sometimes made us hesitate in arriving at a diagnosis.

DR. G. W. JACOBY expressed the opinion that our knowledge of this affection would not be increased much by the study of purely clinical pictures.

DR. E. C. SQUIN related a case of his own, and presented sections of the cord of his patient, stating that they seemed to show that there were instances in which the pathological changes were intermediate between fascicular sclerosis and disseminated sclerosis.

THE PRESIDENT suggested that perhaps the sclerosis followed the course of the minute bloodvessels, whose extensive network, it had been shown, served to connect and bind together the various fasciculi of the spinal cord. This anatomical fact might, he thought, offer a satisfactory explanation of these mixed forms of sclerosis. He regarded the subject of the paper as one of great importance to general practitioners, on account of the frequency with which disease of the spinal cord was now seen.

## NEW YORK NEUROLOGICAL SOCIETY.

STATED meeting, March 1, 1887.

The President, CHARLES L. DANA, M.D., in the chair.

PRESENTATION OF THE CORD AND NERVES IN A CASE OF ALCOHOL PARALYSIS. MULTIPLE NEURITIS.

DR. H. M. BIGGS presented the case. Bertha S., aged thirty-five, married, admitted to the Hospital, September 20, 1886. History imperfect. Nothing of importance in the history up to the beginning of her present illness, about five weeks before admission, when she began to have sharp shooting pains in both legs, but more severe in the right. She began to lose power in her limbs, and one week later was unable to walk because her limbs were "too weak." The loss of power seemed to begin in her feet. She complained of pain in her back and weakness when she tried to stand. Later, she began to have pain and lose power in her arms. She says she has been a moderate drinker, and denies syphilis.

On admission, the patient was almost completely paralyzed in lower extremities; could barely raise her limbs from the bed. The muscles of the upper extremities, especially the extensors, were also somewhat affected. There were some spots of hyperæsthesia and partial anaesthesia irregularly distributed over the lower extremities, and also considerable numbness. Sensation in the upper extremities seemed to be normal. The reflexes were lost. There was marked atrophy in the legs and thighs on both sides, particularly of the extensors of the foot, and a moderate amount in the arms. The extensors here were also most affected. She complained of very severe pain in the arms and legs, which kept her awake at night, and there was marked tenderness on pressure. Temperature at 9 A.M., 100; at 5 P.M., 101.2. Pulse, 9 A.M., 104; at 5 P.M., 112. Urine 1,018; albumin one-eighth in bulk; no casts.

Two days after admission the patient was found to have a moderate amount of fluid in the right pleural cavity. Twenty-four ounces of serum were withdrawn. She gradually failed, lost strength, emaciated; the pleurisy developed into an empyema, for which a free opening was made in the chest. Before death, which occurred in February, 1887, she had lost all power over both lower extremities, and the arms were partially paralyzed. Atrophy was very marked in both lower extremities and forearms. Pain was constant and paroxysmal, and very severe. Tenderness on pressure, and pain on movement of muscles marked. Contraction of the muscles had gradually developed until thighs were sharply flexed on trunk, and legs on thighs. Attempts to straighten the limbs caused the most severe pains. The bladder and rectum, the muscles of phonation, deglutition, and respiration, and the nerves of special sense were entirely unaffected. The reactions of degeneration were present. The patient died of exhaustion resulting from the empyema.

Autopsy: Patient greatly emaciated. Legs and thighs markedly flexed. Muscles of the leg of a yellow color, and apparently converted almost entirely into fat. Muscles of thigh much less affected. Spinal cord, nerve roots and trunks normal in appearance.

Microscopical appearances: spinal cord apparently

normal, with the exception of slight sclerosis in the columns of Goll in cervical region. Nerve roots normal. In one of sacral nerves before its exit from spinal canal was found a marked increase in the endoneurium with diminution in the number of the nerve fibres, and an irregularity and indistinctness in these appearances. The right sciatic nerve showed the same changes more marked. In the posterior tibial the process was even more advanced, and in this only an occasional nerve-fibre could be detected. Microscopically the gastrocnemius was composed almost entirely of adipose tissue; only here and there atrophied muscle fibres were found. The small nerve-trunks in the muscle showed advanced degenerative neuritis, with comparatively little new growth of connective tissue in the nerves.

The president thought that in this case it had been fully demonstrated that the alcohol paralysis was due to a neuritis and not to a myelitis.

DR. M. A. STARR had seen the specimens, and said there was no question with regard to the existence of neuritis in this case, and the normal condition of the anterior cells of the spinal cord. There was slight sclerosis in the columns of Goll which he was unable to explain. The same condition had been observed in a case of Hamilton recorded by Granger Stewart. He referred to a well-prepared specimen by Dr. Van Gieson in a case of Dr. Ball's, not yet published; also to the manner of preparing specimens.

DR. BIGGS said that contrary to the ordinary condition found, the process seemed to be more a degeneration of nerve-fibre, than an interstitial neuritis, especially in the smaller nerves.

DR. NOYES spoke of the frequent occurrence of amblyopia with alcoholism, and said it was due to a partial neuritis of the optic nerve, referred, as had been shown to the centre field, and not to the field at large. He suggested that in cases like the one reported by Dr. Biggs, the neurologists should make careful examination of the optic nerves. In reply to Dr. Starr, whether scotoma was due as frequently to tobacco as alcohol, he said it might be due to either, but the patients frequently combined the two habits.

The president said the name, alcohol paralysis, was rather begging the question; this patient, it seemed, had been only a moderate drinker. The same fact had been noticed in other cases.

Abstract of DR. STEVENS'S paper on

IRRITATIONS ARISING FROM THE VISUAL APPARATUS CONSIDERED AS ELEMENTS IN THE GENESIS OF NEUROSIS.

Two classes of influences were recognized as causes of functional nervous disorders; the remote and the immediate. The remote causes may be sufficient to perpetuate a neurosis when once a nervous irritation has been instituted. While immediate causes rarely induce long-continued disorders, a pre-existing influence may serve to continue it indefinitely. It is of little practical importance that some exciting circumstance has given rise to a nervous trouble. The event has passed and cannot be recalled. If there is an underlying cause it is of much more importance.

Persons in whom underlying causes of neurosis exist, are said to possess a neuropathic predisposition, and those subject to it are liable, from trifling immediate causes, to suffer from various neuroses. In a considerable proportion of cases the neuropathic ten-

deney is hereditary, but the result is not always manifested in the same form in different generations.

A third class of cases which should be recognized may be designated as *modifying tendencies*, among which may be mentioned vitiated atmosphere; the period of life, and the performance of certain physiological functions.

Often as a result of the predisposing influence, when one form of complaint is supposed to be cured, the subject of it is simply suffering from some other form.

Must the predisposing cause of neurosis be central, pervading the whole organism, or must it of necessity be located in the great nerve-centres, or may it be entirely local and outside those great centres? Undoubtedly it may be local, and confined to any portion of the nervous system.

Inasmuch as the tendency is often hereditary, may not the evil consist of some peculiarity of anatomical structure or of physiological adaptations which are inconsistent with the most regular and easy performance of the function of a part or parts; and may not certain classes of mechanical peculiarities be unusually liable to become factors of physiological disturbance?

If we answer in the affirmative, we assume a hypothesis which must be maintained by long-continued observations, conducted in a spirit of judicial independence, and free from the bias which might result from occasional and exceptional experiences. The conclusions announced this evening are based upon observations in more than five thousand cases in private practice, and of a considerable number in public institutions, all of which have been made with as much precision as the exacting demands of an active professional life would permit. The central truth, as arrived at by these observations, may be stated, as it has already been done in a memoir to the Royal Academy of Medicine of Belgium, in 1883, as follows:

Difficulties attending the functions of accommodation and of adjusting the eyes in the act of vision, or irritations arising from the nerves involved in these processes, are among the most prolific sources of nervous disturbances; and, more frequently than other conditions, constitute a neuropathic tendency.

In the proposition, all causes of nervous irritation are recognized. It is held that the influences indicated are preëminent, but not exclusive permanent causes. Let it be remembered that it has been universally conceded that the nature of the neuropathic tendency is unknown. If one preëminently important element is demonstrated, it is not to be rejected because it may not include the whole.

The speaker proposed only to illustrate the result of his experience by exhibiting some photographs of cases of notable neuroses, which showed very remarkable changes of physiognomy, such as habitually occurred when certain hurtful tensions of the ocular muscles were relieved. If he had designed to present only the most remarkable cases of the class to which these belonged, he would have chosen only a few of these. The design was, however, only to show, by these contrasting photographs, the very notable improvement which, in obstinate, and even by ordinary means, hopeless cases of the most important neuroses, might be expected from relief from certain hurtful tensions of the eye-muscles.

The portraits were in pairs, the first having been taken at the commencement of treatment, the second at a later period; the interval being, on an average,

about one month. The first series represented cases in his private practice; the second series, cases which were under his care for a short time at the Willard Asylum for the Insane, last summer. The first series had been made by various photographers; the second by Dr. P. M. Wise, Superintendent of the Willard Asylum. Thirteen pair of photographs were exhibited, nine of the first and four of the second series. In all these, very striking contrasts existed between the first and second portraits.

In No. 1, a weary and listless young girl, a sufferer from headache, and who had never been able to attend school, is seen to be transformed, in twelve days, into a vivacious and thoroughly awake child, following relaxation of each of the inner eye-muscles. The change in health was marvellous. In No. 2, an epileptic girl, whose vacant gaze and half-open mouth indicated a profound degree of dementia, within a single month, put on an appearance of robust health and of lively intelligence. In another case, a boy, choreic from infancy and imbecile, whose constant movements were too rapid, even, for the modern photographer, showed in the second photograph, from which the distortions of the face and wrinkles in the skin had disappeared, a clever mental state.

The speaker related, in brief, some of the results of a short season among the most hopeless cases of the Willard Asylum for the Insane. Two of these hopeless cases, who had, during the month preceding treatment directed to the eye-muscles, been subjected to about one hundred and seventy convulsions, suffered only about forty convulsions in the month succeeding that treatment, notwithstanding the withdrawal of all bromides.

Fifty per cent. of epileptics so treated had remained well for a length of time varying from many years to only a single year, but sufficiently long to indicate that a great change had been wrought. Thirty-two per cent. had received very marked relief, but short of absolute cessation of the complaint. They were all better without drugs than they had formerly been with. In seventeen per cent. no good results had been obtained.

The speaker thought that, with a better understanding on his own part of the extremely complicated condition of the ocular muscles often found in epilepsy, this record could be improved.

The method of procedure in examining for muscular defects was given. It differed radically from that proposed by Grafe, and generally adopted, and from other methods which had been suggested. His method of performing tenotomy was also described.

In conclusion, Dr. Stevens said he thought it was not unreasonable to look for the future advance in medical practice along two great lines: The one related to microorganisms; the other to irregular phenomena, resulting from well-defined causes of irritation, which causes must be sought for principally in the direction of difficulties in the performance of necessary functions. With the removal of such difficulties, we might look with confident expectation to the cessation of the peculiar irregularity which constituted the special form of nervous disease.

DR. E. C. SEGUIN said, with regard to the ætiology of neuroses and serious mental disorders, that he thought we ought to look a great deal deeper than the exciting and superficial causes which occurred in many cases of that kind. In epilepsy and chorea, for instance, he thought we had to look for the efficient

cause, not in disturbed external apparatus, but to hereditary predispositions and faulty tendencies. That faulty external apparatus would cause more attacks, or possibly aggravate the mental disorder, he thought no one would deny. Consequently, the optic apparatus, the genital apparatus, etc., should be put in perfect order. As to the great improvement after tenotomy in epilepsy, the records of surgery and medicine were filled with cases, in which trauma of various kinds had interfered with epileptic manifestations for months, or even years. It seemed to him, the report of a case within six months after tenotomy was rather premature. He referred to one of his cases of epilepsy recently submitted to division of the ocular muscles, the bromides, at the same time being withdrawn; and three days later she commenced to have from six to twelve convulsions in the twenty-four hours—more than she had ever had before the operation. He had had patients go three years without an epileptic attack, and then have a relapse.

DR. H. D. NOYES thought the precise ocular conditions of the cases reported should have been recorded; perhaps they were in that part of the paper not read. He had with him exact records of a number of cases of ocular trouble, with the result of treatment. It had not fallen within his experience to meet with the class of cases referred to by Dr. Stevens. He dwelt upon the importance of making a thorough ocular examination, including that of the muscles of the eye, in every case. He had come to realize more and more the importance of insufficiency of the external recti. He had obtained benefit in many cases from prisms. He spoke of the method of examination and of performing tenotomy. The paper deserved the most careful consideration.

DR. D. B. ST. JOHN ROOSA said that that part of the paper which especially concerned the ophthalmologist was as old as ophthalmology itself, and it did not call for discussion to-night. The real point in the paper was, he thought, that the correction of errors of refraction, improper relation between the ciliary and internal recti muscles, and other deviations of the ocular muscles, was capable of curing constitutional disease. He took it that epilepsy was a constitutional disease, and not merely a functional disturbance. The same was true of chorea. The question was: Did these operations cure epilepsy and chorea? But it had been shown that people with chorea got well without ever having errors of refraction corrected. It had also been shown that the vast majority of people who were not myopes were hypermetropes, yet suffered no inconvenience from it. In this, the author's second paper, another step had been taken, namely, that these constitutional diseases—epilepsy and chorea—were due, not solely to error of refraction, but to want of coordination between the recti and ciliary muscles. Then the prism test came upon the field, and we had to exercise the ocular muscles by prisms. Then, in the order of advance, came the doctrines taught in the paper of to-night. Granting the claims of the paper—that the patients had for a time after correction of an ocular difficulty been greatly relieved, possibly cured—yet that was a long way from assuming that the ocular disturbance, whatever it was, was the cause of the epilepsy. Many great men having strabismus had not become choreic, epileptic, or insane.

DR. A. L. RANNEY thought that, following the exhibition of the photographs, little need be said in con-

firmation of the views advanced by Dr. Stevens. The photographs were so startling that they would be accepted in any court of justice, by an unprejudiced jury, as proof that unmistakable benefits had been derived from the treatment. He had, personally, seen and examined several of the cases, and he considered the published histories as decidedly under-estimated. Dr. Ranney had performed the operation for the relief of ocular insufficiency nearly two hundred times; and had carefully examined the condition of refraction and accommodation, as well as that of the ocular muscles, in several hundred subjects afflicted with various forms of nervous disease. He did not pretend to pose as an oculist, but as a neurologist. Originally, he was a skeptic; but his skepticism became no longer tenable when he saw a choreic and epileptic imbecile in Dr. Stevens's office, who was perfectly restored in a short time to health and mental sanity by the method he had described. He thought the paper would tend to establish a new era in neurology. Regarding the operation, in no case had he had bad effects from it, but the treatment required careful regard to detail.

Respecting the view that the eye is an important factor in creating and prolonging the so-called "neuropathic predisposition," the following facts were pertinent:

(1) No one has yet shown in what this predisposition lies. Hence, if Dr. Stevens has shown that eye-defect is an important element in these conditions, a great advance has been made.

(2) There is no recognized pathology in functional nervous diseases.

(3) Heredity is very common in these affections.

(4) My records, in common with those of Dr. Stevens's, go to show that eye-defect is found in a very large proportion of such subjects.

(5) Many of the eye-defects found can be shown to be congenital, being inherited, like feature.

(6) The manifestations of the neuropathic predisposition vary with each case, and are called forth often by trivial circumstances, which are too frequently regarded as of great clinical interest.

In the treatment of the severer forms of functional nervous disease (for example, in chronic epilepsy), one radical cure without the use of drugs offsets a thousand failures, as a proof of the scientific value of a discovery. Dr. Stevens had seven cases free from epileptic seizures for more than five years after tenotomy of the eye-muscles, and without the aid of drugs. This could not be explained by chance. Then the records of the Willard Asylum were hard to contradict.

During the past year and a half he had seen sixteen epileptics in private practice; in only one was no defect of the eye-muscles found. He had an opportunity to operate on the eyes in eight of the cases: Three of these were cured; two had had no fits for over one year. In the five cases still under observation, the attacks had been lessened in all, drugs having been withdrawn. One had been reported by Dr. Stevens. In headache and neuralgia, he had some very remarkable results from tenotomy of the eye-muscles; also satisfactory results in hysteria and hystero-epilepsy.

DR. HERMAN KNAPP said his practice had not brought him much in contact with people who had neurotic conditions, and most of those whom he had seen had passed into other hands. He was very much surprised to learn that there was so high a percentage of ocular difficulties in the patients Dr. Stevens ex-

amined in the Asylum. He thought nervous people generally showed not only one complaint. Many people, especially young ladies who suffer from headache, etc., cease to complain after correction of a deviation of the eye muscles, etc. He had listened with the greatest attention to Dr. Stevens; and he felt quite sure that his work was not only legitimate, but that it was highly promising. He was only afraid we would not be spared disappointments in that line of treatment.

DR. GRUENING said his experience had been very much like that of Dr. Knapp. He always examined for muscular defect, and said that when one placed a prism before the eye, it disturbed binocular vision. For the correction of this apparent muscular defect an operation was performed; but the muscle was sewed to its original place, or the lateral attachment was not divided, and this was only the simulation of an operation. He had benefited many patients by cylinders.

DR. STEVENS, in closing the discussion, said there was no suggestion in the paper regarding cures. He did not believe in cures. Take away the cause of the trouble, and they got well. If the patients could not be said to be cured, it was still a very fortunate thing that they had got rid of their chorea, epilepsy, etc.

#### CHICAGO GYNÆCOLOGICAL SOCIETY.

REGULAR meeting, Friday, January 21, 1887.

The President, CHARLES WARRINGTON EARLE, M.D., in the chair.

DR. CHARLES T. PARKES made the following remarks upon

#### A CASE OF INTERSTITIAL PREGNANCY, WITH REMOVAL OF THE PRODUCT OF CONCEPTION THROUGH THE UTERINE CAVITY,

with the exhibition of the specimen.

The specimen, which I exhibit to-night, comes from a case, which has been of extreme interest to me, and is, I think, the remains of a conception, which was certainly outside of the uterine cavity, and which I succeeded finally in delivering through the womb. It was taken from a lady, thirty-three years of age, who seven years ago, was delivered of a child at full term. The child is now living. A year after that, she was taken with hemorrhage and had quite a severe bleeding, every month or second month, for two years. Some time after her pregnancy, she was operated upon for laceration of the cervix, but the operation had little effect upon the hemorrhage. Two years ago she again became pregnant, and was delivered at the proper time. This child is still living. The lady came under my charge last September, for hemorrhage from the uterus. On examination I found a globular mass in the lower portion of the abdomen, as large as two fists, very hard and tense. When I felt it through the abdominal walls, my impression was that it was a fibroid growth. Upon digital examination, I found the cervix dilated sufficiently to admit the finger very readily, which went over the surface of a smooth mass in the uterine cavity. This led me to think that it was a fibroid tumor with a broad base, probably a submucous tumor, which gave rise to the

hemorrhage. On that supposition I placed her on the ergot treatment and kept it up for a week, twenty drops of the fluid extract every six hours. This gave rise to such severe attacks of pain that the patient could not bear the treatment any longer, but it had the effect of diminishing the flow of blood and increasing the dilatation of the cervix. I took pity on her on account of the pain and gave a couple of hypodermic injections of morphine; when the pain ceased, the cervix began to contract again and soon reached its normal size, and the patient recovered from the acuteness of the disturbance, but the hemorrhage still continued, accompanied with a flow of mucus. I attended her from the 16th of September until the 14th of October; as she was getting along pretty well, I supposed the action of the ergot would gradually force this mass down so that it could be removed. My visits ceased and I heard nothing more from the patient, except an occasional report that she was getting along in the same way, until the 10th of December, when her husband came into my office and showed me a little piece of bone, or a piece of hard substance that looked like bone, which he said his wife had picked off the napkin. It had the appearance of fetal cranial bone. He asked me what it meant, and I told him I could not say, but would see his wife. On inquiry, I found that the flow of blood had ceased, but the flow of pus had increased, and occasionally there was extruded a piece of this bony substance. On digital examination, I discovered the os and cervix filled with particles of this bony substance, and after removing them I found it impossible to introduce my finger into the cervix. The external tumor was reduced considerably in size, and was low down in the pelvis, and could be felt projecting through the anterior vaginal wall. I then decided to dilate the cervix. I introduced as many tupelo tents as I could get into the cervix—at first but two of fair size—to their full length, and allowed them to remain there over night, when I removed them and introduced four more. That evening I removed them, and the cervix was dilated so that I could easily introduce my finger. As I had examined the uterus with the sound at my first visit, and it went around this mass to its full length, I supposed I had nothing but a fibroid to deal with. When I had dilated the cervix with these tupelo tents, I found I could not get at the mass of the growth, my finger going into the cavity of the uterus. At the distance of one joint and a half inside the cervix, I found a little opening, and projecting through this opening—about as large as the end of a pencil—were some of these particles of bone. Then the query arose, how was I to get into this cavity, and what was it? a double uterus, with multiple pregnancy at the last conception—one delivered and the other retained? I was at a loss to know what it was, but finally concluded it to be an intra-mural pregnancy. I had the particles examined under the microscope, and they showed the structure of fetal bone. Then I thought of using the tents, to increase the dilatation, but was troubled with the fear that I should have a severe septicæmia come on as soon as this outside cavity was opened to air. But I was convinced that unless I tried to do something, the patient would pass out of my hands; so I decided to keep on with dilatation. On the 20th of December I began introducing the tents, and within two or three days after their removal, the cervix was again contracted so that it would not

admit the finger. I introduced the tents again, and met the same difficulty in exposing the mass. The thought struck me that if I could not get the large body out of the small opening, I could diminish the size of the mass; so I introduced small forceps into this opening, and took it away piecemeal. All this time I had the entire uterus under my command, because it was an easy matter to bring the cervix down to the vulvar orifice. On the 24th, I introduced tents and dilated it, so that I could introduce two fingers very readily, and finally got one of my fingers into the opening in which this body (indicating the specimen) was found. I then began to separate it and pull it away, getting hold of it with strong forceps. Sometimes I succeeded in bringing away a large mass of flesh, which looked exactly like that from a macerated fetus, the skin macerated and parchment-like. This was continued up to the 30th. Passing over the New Year, and allowing the patient to rest without interference, on January 9th, I introduced four tupelo tents, a little longer than the ordinary, and fortunately succeeded in getting one or two into the opening in which the body was found; so when I removed them that evening, I was enabled to bring away the entire mass and pass the finger into the cavity afterwards. It was very irregular, as though the uterine tissues had been forced into the irregularities of the foreign body. Since that time the patient has improved, the bleeding has ceased, the uterus has diminished in size, and she is up and about the house. I have had all parts of this specimen examined under the microscope. The fleshy mass shows connective tissue, muscular fibres, blood-vessels and hairs. The osseous material shows all the characteristics of fetal bone.

## DISCUSSION.

The PRESIDENT. Was there a history that would lead you to suppose, that at any time during her invalidism there was a pregnancy, or a pelvic hematocoele, or anything of that kind?

DR. PARKES. At the time of her last pregnancy, she was very large and yet was delivered of a child that weighed but six pounds. Her abdomen was very large for some time after the delivery of this child. Again, there is a history several years back, of a period when menstruation ceased, and she supposed she was pregnant, but nothing came of it.

DR. W. W. JAGGARD said the interesting specimen presented by Dr. Harkes was a typical lithopædion—a calcareous capsule, containing the fetal structures infiltrated with lime salts.

He thought the diagnosis of interstitial pregnancy highly probable. It was impossible to make a positive diagnosis without a post-mortem examination of the maternal organs. Carl Braun<sup>1</sup> was responsible for the statement that the formation of a lithopædion occurred only in case of extra-uterine pregnancy. Spiegelberg,<sup>2</sup> however, indicates that this proposition is too general. The formation of a *uterine lithopædion* occurs infrequently in the human female, but is not unusual in ewes. Koerber<sup>3</sup> extracted by abdominal section a lithopædion from the rudimentary horn of a *uterus bicornis*.

The formation of a lithopædion, therefore, was not a reliable sign in the differential diagnosis between uterine and extra-uterine pregnancy.

## RHODE ISLAND MEDICAL SOCIETY.

GEORGE D. HERSEY, M.D., SECRETARY.

THE usual quarterly meeting was held in Providence, March 17, 1887, the President, DR. HORACE G. MILLER, in the chair.

A communication was received from the Secretary of State, announcing that the General Assembly had amended the charter of the Society, granting power to hold real and personal property to the amount of one hundred thousand dollars. The Society voted to accept the amendment.

The President appointed a Building Committee of five members, namely, Drs. J. H. Eldredge, of East Greenwich; Lloyd Morton, of Pawtucket; and J. W. Mitchell, G. T. Swarts, and G. D. Hersey, of Providence.

DR. GEORGE L. COLLINS was appointed to serve on the Library Committee, in place of Dr. O. C. Wiggins, resigned.

Delegates to the American Medical Association were elected as follows: Drs. H. G. Miller, Albert Potter, J. W. Mitchell, J. H. Eldredge, George W. Jenckes, A. G. Browning, H. Canfield, L. Morton, G. T. Swarts, W. R. White, M. Fifield, J. H. Morgan, H. Terry, A. E. Tyng, H. R. Storer, C. V. Chapin, W. J. Barge, and W. B. Goldsmith.

DR. F. T. ROGERS reported

## A CASE OF TUBAL PREGNANCY.

The patient, twenty-two years of age, married three years, fell unconscious from her chair in a hotel dining-room, and was carried into an adjoining waiting-room, where unavailing efforts at resuscitation were made. On the physician's arrival, he was unable to revive the patient with hypodermic injections of brandy and ammonia, and she died two hours after the attack, no history of pregnancy having been obtained. It was afterwards learned, however, from her husband, that she had passed the catamenial period two weeks; and a *post-mortem* examination revealed a six-weeks fetus in the dilated right Fallopian tube, a ruptured sac, and copious hæmorrhage into the abdominal cavity. In this case no accurate diagnosis could be made, on account of the imperfect history; and laparotomy, the only possible procedure offering relief, was not suggested.

Dr. Rogers also presented photographs of an unusual monstrosity. A female child, weighing eight and a half pounds, had a soft tumor at the base of the cranium, nearly as large as the head, and a shining, tense enlargement of the labia majora, to which the funis was attached. Dissection was forbidden by the parents; but, fortunately, a good photograph of a frozen section in the median line was secured. The occipital was entirely disconnected from the other cranial bones, having a rudimentary foramen magnum, but no articular condyles. The first cervical vertebra articulated with what was probably the sphenoid, and the vertebral column terminated between the spines of the scapulae. Between this point and the pelvis there was no bony structure. The anterior tumor contained brown, gelatinous fluid, with some folds of intestines. The anus was imperforate.

DR. C. M. GODDING exhibited a carefully-mounted specimen of malformation from an infant which lived two days. The rectum and bladder emptied into a common cloaca, with which a rudimentary uterus was

<sup>1</sup> Lehrb. d. g. Gynæk., 1861, p. 128.

<sup>2</sup> Lehrb. d. Geburtshilfe, 1882, p. 312.

<sup>3</sup> Glas, hebbl. No. 34, 1886.

also connected. The child had also a malformation of the heart, there being an entire absence of the ventricular septum.

Dr. W. R. WHITE reported

A CASE OF ACUTE INDIGESTION IN A PRIMIPARA, aged eighteen years, who had eaten a hearty Thanksgiving dinner the day previous. At the beginning of the second stage of labor, the pulse, previously 80, suddenly fell to 48, and fetal heart-sounds could no longer be recognized. Labor was speedily completed, and the child, apparently dead, was resuscitated with difficulty. The mother's pulse remained at 48; she complained of headache and photophobia, and in the evening was delirious, with a temperature of 102°. These serious symptoms all disappeared after profuse vomiting; pulse and temperature became normal, and the patient made a good recovery.

Dr. ELY suggested that toxic ptomaines developed from fermenting, undigested food might cause such results as were described.

Dr. E. B. SMITH reported

A FATAL CASE OF PULMONARY GANGRENE FROM PYEMIA, FOLLOWING AN ABSCESS IN THE GLUTEAL REGION.

The patient, a woman, aged twenty-two, had otherwise been in good health.

Dr. R. F. NOYES reported

A CASE OF HYDATIFORM TUMOR OF THE LIVER, and exhibited mounted specimens of the echinococcus. The patient, a stevedore, aged forty-two, was admitted to Rhode Island Hospital, with pulse 110, respirations 30, and temperature 100°. The liver somewhat enlarged, its surface smooth. No nodules or tumor could be felt. Tenderness and pain were caused by pressure over the posterior portion of the right hypochondrium; and spontaneous pain was complained of in this region, and through the right thorax and shoulder. Examination of the chest revealed nothing abnormal, except that hepatic dulness was higher than normal. Considerable cough and expectoration, the sputa containing numerous cells, resembling pearls of tapioca. The day following, the pain increased; pulse and respirations were more hurried; temperature sank to 97°, and there was marked bulging of the right side of the thorax, with flatness on percussion, and almost entire absence of respiratory murmur. The patient became cyanotic, and died two days after admission.

Autopsy. The thoracic cavity contained five pints of yellowish opalescent fluid, floating in which were a multitude of small cysts. The parenchyma of the lung was ulcerated in several places and communication thus established with the bronchi. Upon the under surface of the right lobe of the liver was found a cavity of the capacity of three pints, filled with yellowish fluid in which were thousands of transparent cysts. The cavity communicated with the thoracic by an ulceration through the diaphragm.

Dr. G. T. SWARTS read a paper on the

PURIFICATION OF WATER FOR DRINKING PURPOSES, and exhibited and explained the construction of the Luther, Aborn, Acorn, Gem, Ideal, Diamond and Howe filters, and gave the results of a series of experiments he recently made to test their value in filtration of micro-organisms. These filters were arranged

upon the same line of pipe in the Bacteriological Laboratory of Harvard Medical School. A faucet was left on the same line of pipe beyond the filters for drawing the water for the unfiltered analysis, and a faucet beyond that to draw off any sediment which might accumulate, as is usually the case in a "dead end," however small the pipe.

All the filters were tested at the same time and under the same conditions as follows:

Water was drawn from the last faucet until it was evident that all air and detritus had been washed from the section of pipe to which the filters were attached. About four litres of water was then drawn through each filter to remove any dirt and dust which might be left in them from packing and putting together. From each filter 50 cc. of water was then drawn into a sterilized Erlenmeyer's flask having a sterilized cotton plug. One cc. was then taken from the flask with a sterilized pipette and mixed with 10 cc. of sterilized nutrient ten per cent. gelatine (Koch's formula), and flowed upon a sterilized glass plate, which was placed upon a glass slab over a jar of powdered ice, and the whole protected with a sterilized bell-jar until the gelatine had hardened. This plate culture was then placed in a sterilized glass chamber with moisture, and allowed to remain for forty-eight or seventy-two hours in a room at a temperature of 70° F., at the end of which time each individual microbe or micro-organism introduced with the water into the gelatine, has grown by its own multiplication an individual colony. The colonies in each culture were then carefully counted and compared with a similar culture made with unfiltered water.

The results obtained show that some filters on the first use successfully removed a certain proportion of organisms from the water. A test made seventeen days later showed in every case a marked increase in the number of colonies in the filtered as compared with unfiltered water. For instance, the unfiltered water contained thirty-six colonies of growth while the filtered water showed the presence of colonies to the number of 2,000, 9,000, and 10,000. An examination on the seventieth day showed an increase in case of one filter, of 117,000 colonies.

Other experiments were made to determine how far the consumer could cleanse his filter or sterilize it in some simple manner. The results showed, however, that even with every possible precaution, the number or organisms in filtered water exceeded the number in the unfiltered by several thousands.

These experiments go to show conclusively that the organic matter retained in the meshes or interstices of the filtering media, contain organisms which increase rapidly while the filter is or is not in use, and especially if its position is in a heated kitchen or in proximity to a hot-water pipe.

---

—The late Dr. Wakley, editor of the *Lancet*, bequeathed to his *alma mater*, University College, London, his freehold residence, Heathlands, Longcross, Chertsey, and eight acres of land, for the uses of a convalescent home for patients from that hospital, to be called the Wakley Convalescent Home, in memory of his late father, Thomas Wakley, the founder of the *Lancet*. He also gave \$5,000 towards the maintenance of the Home.

**CACHEXIA STRUMIPRIVA.**

At the Naturforscher-Versammlung in Berlin, on September 23, 1886, the connection of this affection with total extirpation of the thyroid gland was discussed.<sup>1</sup> Eighteen cases in which the operation had not been followed by cachexia strumipriva were reported by Baumgärtner and Bardeleben. The former thought that many of the dangers attending the operation could be avoided by improved technique; and that it would be wrong to reject the procedure as unjustifiable. No satisfactory explanation of the apparent connection of cachexia strumipriva and thyroidectomy was offered.

Notwithstanding the above opinion it is far from being universally accepted that one can surely avoid such disastrous consequences of the operation in question as cachexia strumipriva or tetanus, and in view of this fact partial resection,<sup>2</sup> extirpation of the isthmus, and parenchymatous injection, or electrolysis have been recommended as substitutes.

But these methods, aside from not being always applicable, have also several disadvantages which influence unfavorably the result of the operation.<sup>3</sup> For this reason Wölfler<sup>4</sup> proposes anew<sup>5</sup> the ligation of the thyroid arteries, and claims that the former failures following this procedure were due to secondary hæmorrhage resulting from unskilful or improper after-treatment of the wound. Also that the inferior thyroid artery was not ligated. Wölfler found that ligation of the thyroid arteries in dogs was followed by a marked contraction of the gland without gangrene ever occurring. Accordingly in a male patient, aged twenty-nine, whose uniformly enlarged gland had caused alarming dyspnoea, Wölfler ligated the right superior and inferior thyroid arteries. The result was surprisingly satisfactory; for not only was

the patient rescued from immediate danger, but seven months later the right lobe was found to have contracted to less than one-half its former size, while the left had also become somewhat smaller. The anatomical reasons for the ligation of both superior and inferior arteries, and the technique of the operation, are fully stated in the original publication of the author.<sup>6</sup> Attracted by Wölfler's success on October 8, 1886, Weinlechner<sup>7</sup> ligated both superior thyroid arteries in a patient whose right thyroid lobe equalled in size a man's fist. The left lobe was also enlarged but to a less degree. The indications for operative interference were excessive dyspnoea, and cyanosis. The reported result was even more striking and satisfactory than in Wölfler's case; for on the twenty-seventh day after the operation the gland was found to measure seven cm. less in circumference than at the time of its performance, while in Wölfler's patient, when the inferior and superior thyroid arteries on the same side were ligated, the amount of contraction recorded at the end of seven months was only six cm.

The marked success of these cases surely warrants a thorough test of this method and their final termination will be awaited with deep interest, especially since a review of the investigations and opinions regarding the function of the thyroid, and the results caused by its removal in man and animals, shows thus far only a conflict of opinion. One class of observers believes that the function of the organ is unimportant to the animal organism, while an opposite view is held by the opponents to this theory.

This unsatisfactory state of uncertainty and the importance of discovering the true value of surgical treatment in these distressing cases has incited F. Fuhr<sup>8</sup> to an extensive series of experiments for the purpose of ascertaining: (1) If the thyroid gland is an organ important to life. (2) An explanation for the contradictory opinions and experimental results. (3) In case thyroid extirpation is unimportant what explanation there is for the remarkable group of symptoms reported to have followed the operation by so many different observers. The conclusions of this laborious and carefully conducted investigation are: (1) That extirpation of the thyroid gland in dogs, whether complete at one operation or gradual, is always fatal with symptoms referable to disturbances of the central nervous system. The significance of these symptoms is not, however, positively established since an organ whose function is presumably that of regulating the blood tension of the central nervous system, and especially of the brain, has been annihilated. (2) The group of symptoms that the dogs presented cannot be the result of some injury of surrounding structures at the time of operation, or of a septic process. (3) If a dog survived the operation it was because at least one third of the main gland remained in the form of one or more accessory glands. (4) That other experimenters who have obtained dif-

ferent results have either mistaken other structures for the thyroid, or have failed to completely remove the true gland. Fuhr concludes by saying that physiologically it does not require another half-hundred of unfortunate victims to prove the doubtful value of total extirpation whatever may be its justification from the present surgical standpoint.

That the above results are correct, time and subsequent experience can alone demonstrate, but they are surely rational, and if true will go far to harmonize the conflict of opinion now met on every hand.

Before dismissing this important subject it is perhaps advisable to call attention to another expedient to avoid the dangers apparently consequent to total extirpation offered by the intracapsular enucleation operation of Professor Socin, the so-called intra-glandular or "shelling out" removal of the diseased areas only, which Garré,<sup>2</sup> of Bâle, has strongly advocated. It is assumed that total extirpation is an unjustifiable operation, and in a large proportion of the cases of goitre submitted to operation the disease appears in circumscribed masses, each separated from healthy gland tissue by a capsule of greater or less thickness. The operation consists in "shelling out" these diseased centres after opening the capsule. To those interested in this method Müller's report of Brun's<sup>3</sup> cases is of value.

The latest reports in regard to the results of applying electrolysis to goitre seem to promise safe and favorable results.

#### THE FOURTH DECENNIAL CENSUS OF MASSACHUSETTS.<sup>1</sup>

The first part of the first of the three volumes on the Census of 1885 is devoted to population and social statistics, as Part II will also be. Volume II will deal with manufactures, the fisheries and commerce; Volume III will relate to agriculture, property, mines, pits and quarries, both to be ready this year.

The collection of statistics has been by 570 enumerators appointed by the Bureau of Statistics of Labor, as required by law, upon the recommendation of selectmen of towns and mayors and aldermen of cities; the result of which has been that the head of the bureau recommends that in future enumerators be appointed by the Civil Service Commission, as the clerical force is already appointed. The work, as a whole, is very satisfactory, however, the bad work of the enumerators "who proved unfit for any duty requiring care and integrity" having been supplemented by re-enumerations or by careful corrections.

The population increased 290,229 from 1875, from 1,651,912 to 1,942,141 or 17.57 per cent. as compared with 30.38 per cent. from 1865 to 1875.

The males in 1875 numbered 794,383, and repre-

sented 48.09 per cent. of the population, whereas the females were 857,529 in number, or 51.91 per cent. In 1885 the males numbered 932,884, or 48.03 per cent. of the population, while the females numbered 1,009,257, or 51.97 per cent., an excess of females over males of 76,373, or 108.19 females to 100 males. In 1840 the excess of females over males was but 7,672, or 102.13 females to every 100 males; in 1855, 32,301, or 105.87 females to every 100 males; in 1865, 63,011, or 110.46 females to 100 males; in 1875, 63,146, or 107.95 females to 100 males. Two cities representing a population of 42,486, or 2.19 per cent. of the whole population, show an excess of 1,756 males, while 21 cities, with a population of 1,045,010, or 53.81 per cent. of the total population, show an excess of 58,000 females. 124 towns, having a population of 229,816, or 11.83 per cent. show an excess of 5,706 males, while 198 towns, representing a population of 622,955, or 32.07 per cent. show an excess of 25,835 females.

Boston and its suburbs, representing 574,249 people, contain 29.57 per cent. of the entire population of the State. The same cities and towns had in 1875 a population of 480,419, the gain within this limit during the past ten years being 93,830, or 19.53 per cent. The cities and towns within a radius of twelve miles from the State House have a population of 731,746, or 37.68 per cent. of the population of the State. The population of the cities and towns within this circle in 1875 was 603,909, a gain of 127,837, or 21.17 per cent. during the last ten years as compared with 17.57 for the State, or 23.66 per cent. for the cities and 10.64 per cent. for the towns. Boston, with a population of 390,393, comprehends 20.10 per cent. of the population of the State; eight towns, ranging in population from 30,000 to 70,000, represent 20.84 per cent. of the population; 22 towns, ranging in population from 10,000 to 30,000, represent 20.06 per cent.; 85 towns, ranging in population from 3,000 to 10,000, represent 22.60 per cent., while 232 towns, ranging in population from less than 500 to 3,000, represent 16.40 per cent. only.

Massachusetts has a population of 241.56 to the square mile. In 1880 it had 221.8 to the square mile as compared with Rhode Island 259.9, New Jersey 151.7, Connecticut 128.5, New York 106.7, Pennsylvania 95.2, Maryland 94.8, Ohio 78.5, Delaware 74.8, Minnesota 9.8, Texas 6.1, the United States 13.92, Belgium 481.71, the Netherlands 312.86, Germany 216.62, Switzerland 177.10, Austria-Hungary 156.98, Great Britain and Ireland (1881) 289.92, France (1881) 180.88.

By law, every male twenty years of age residing in the State on the first day of May in any year, and not a pauper or exempt by law, is a poll, and should be taxed as such. The Census reports the number of such persons on May 1, 1885, to be 567,959, this number being 29.24 per cent. of the whole population. Of this number 442,616, or 77.93 per cent. of the whole number of polls, are given as legal voters;

<sup>1</sup> The Census of Massachusetts, 1885. Prepared under the Direction of Carroll D. Wright, Chief of the Bureau of Statistics of Labor. Volume I. Population and Social Statistics, Part I. Boston, 1887.

<sup>2</sup> Centib. f. Chir., 1886, No. 45.

<sup>3</sup> Intracapsular Extirpation of Thyroid Cysts. E. Müller. Ann. of Surg., August, 1886.

26,212, or 4.62 per cent. of the number of polls, as not voters; and 99,131, or 17.45 per cent. as aliens; that is, men of foreign birth, who have not secured citizenship.

The whole number of voters, those who might vote were it not for non-payment of poll-tax or failure to become naturalized, is 412,616, as against 351,113 in 1875; the voters in the latter year formed 21.25 per cent. of the whole population, while now they constitute 22.79 per cent. Of the 99,131 aliens 35,600 are Irish, 33,754 from British America, 13,937 from Great Britain, 14,578 from various countries of Europe, 347 from China.

The whole number of aliens in the State, or 99,131, constitutes 48.07 per cent. of the whole number of foreign born males 20 years of age and over, the latter being 206,227; that is to say, of the latter number of foreign born males 20 years of age and over, 48.07 per cent. have not been naturalized. This total number of aliens as distributed by place of birth shows some interesting features. For instance, of the total number of males 20 years of age and over born in British America, or 49,534, those not naturalized are 33,754, or 68.14 per cent. They are subdivided, as follows: of 5,307 English Canadians, 3,181, or 59.94 per cent.; of 22,427 French Canadians, 17,292, or 77.10 per cent.; of the total number of males 20 years of age and over born in Nova Scotia, or 13,645, those not naturalized, or aliens, number 8,703, or 63.78 per cent.; of 5,041 males 20 years of age and over born in New Brunswick, 2,799, or 55.52 per cent., are not naturalized; of 1,011 males 20 years of age and over born in Newfoundland, 470, or 46.49 per cent. are not naturalized, while 1,303 out of a total of 2,090 males 20 years of age and over born in Prince Edward Island, or 62.34 per cent., have not become naturalized. The Chinese males 20 years of age and over number 383; of this number 347, or 90.60 per cent. are still aliens. The foreign born males 20 years of age and over from the Continent of Europe, not including Great Britain and Ireland, number 25,408; of this number 14,578, or 57.38 per cent., are still aliens. The highest percentage of aliens coming from Europe is shown for Italy, there being 2,190 males 20 years of age and over and 1,874 aliens, or 85.57 per cent. The aliens born in Portugal, or 2,175, represent 75.05 per cent. of the 2,898 males 20 years of age and over born in that country. The Germans have naturalized to a large extent, for out of 10,908 males 20 years of age and over, 4,473, or 41.01 per cent. only, have not become citizens. Looking at Great Britain and Ireland, we find that the Irish born males 20 years of age and over number 98,199, of which number 35,600, or 36.25 per cent. only, are still aliens, the Irish thus ranking all other nationalities in the extent to which they become naturalized. Of the English males under consideration, 45.00 per cent. have not become naturalized, while 49.76 per cent. of the Scotch have not taken on American citizenship.

The average size of families is 4.58. Blacks (10,446), mulattos (5,038), Chinese (278), Japanese (10,) and Indians (520), constitute the same percentage of the population as in 1875, namely, 0.99.

The number of single males is 531,113, or 56.98 per cent. of the whole number of males, while the number of single females is 539,038, or 53.41 per cent. The number of married males is 368,457, or 39.50 per cent. of the whole number of males, while the number of married females is 371,129, or 36.77 per cent. The total married persons number 739,586, or 38.08 per cent. of the whole population. In 1875, 39.06 per cent. of the whole population were married. The number of widowed males is 32,154, being 3.45 per cent. of the total number of males, while the number of widowed females is 97,158, or 9.63 per cent. The divorced males number 1,037, while divorced females number 1,919. This difference is undoubtedly due to the fact of desertion on the part of the husband, leaving the wife within the Commonwealth to seek her divorce.

In 1885, 688,284 males, or 73.78 per cent. of the total males, are native born; and 244,600, or 26.22 per cent., foreign born, as against 74.86 per cent. native born and 24.68 per cent. foreign born, respectively, in 1875. For females, 726,990, or 72.03 per cent., are native born, as against 73.60 per cent. in 1875; and 282,267, or 27.97 per cent., are foreign born, 25.98 per cent., in 1875, being foreign born.

Of native born males, 20 years of age and over, 32.20 per cent. are single, and 62.19 per cent. are married. Of foreign born males of similar age, 25.90 per cent. are single, and 67.92 per cent. are married. For single females, the percentages are 29.09 for native born and 25.67 for foreign born; while, for those who are married, we find 57.97 per cent. foreign born, and 56.16 per cent. native born.

The number of males 80 years of age and over in the State is 5,892, and of females, 9,624. The average age for males is 28 years and 3 months; 29 years and 2 months for females; and 28 years and 9 months for both sexes. In 1875, the average age for males was 27 years and 6 months, and for females, 27 years and 10 months, or an average age for the whole people of 27 years and 8 months. The average death age for 1885, as given in the Massachusetts Registration Report, is 34.23 years. The average age of the population above 20 years is, for males, 40 years and 7 months; for females, 40 years and 11 months.

A very interesting table is given of the nativity of the population, the abbreviations used being *n*, for native; *f*, for foreign; and *unk*, for unknown.

The total population of the city of Boston, or 390,393 persons, includes 121,720 native born persons of native parentage, which is 47.34 per cent. of the whole number of native born persons in the city; while there are 503 foreign born persons of native parentage. Of the whole number of persons having foreign parentage, 102,786, or 39.98 per cent. of the total native born, are of native birth, that is, were born in

this country. The total number of foreign born persons having foreign parentage is 130,896, or 98.20 per cent. of the total foreign born, making a total of 233,682 persons, or 59.86 per cent. of the total population of the city having foreign parentage. The persons of native parentage represent 31.31 per cent. of the total population; and persons of mixed and unknown parentage, 7.16 and 1.67 per cent., respectively.

PARENT NATIVITY	Popula'n	NATIVE BORN.		FOREIGN BORN.

There are 576,597 persons in the State whose mothers were born in Massachusetts; of this number of persons, 575,092 are native born persons, and 1,505 foreign born persons. Of the whole number of persons having mothers born in Ireland, or 556,952 persons, 293,245 are native born, that is, born in this country, while 263,707 are foreign born. The total number of persons having fathers born in Ireland is almost exactly the same as for persons having mothers born in that country. For Great Britain, there are 132,333 persons in Massachusetts having fathers born somewhere in Great Britain, and 119,804 persons whose mothers were born in Great Britain. Although 72.87 per cent. of the persons are native born, but 48.05 per cent. of the total fathers, and 48.89 per cent. of the total mothers, are native born. The total persons born in Massachusetts represent 57.54 per cent. of the total population; but the fathers born in Massachusetts represent only 29.87 per cent. of the total fathers, and the mothers born in Massachusetts but 30.28 per cent. of the total mothers. Analyzing the percentages of foreign born, we find that the foreign born persons constitute 27.13 per cent. of the total persons; while the foreign born fathers constitute 51.95 per cent. of the total fathers, and the foreign born mothers 51.11 per cent. of the total mothers.

There are 568,633 persons in the State whose fathers were born in Massachusetts. Of this number of fathers, 449,140 married Massachusetts born women; 83,013 married women born in other parts of the United States, while 31,443 married foreign born women. There are 346,081 persons who had fathers born in other parts of the United States than Massachusetts, these fathers marrying 79,450 Massachusetts born women, 243,888 women born in other parts of the United States, and 20,643 foreign born women. There are 988,810 persons whose fathers are foreign born. Of these foreign born fathers, 42,648 married

women born in Massachusetts; 25,008 married women born in other parts of the United States, while 919,869 married foreign born women.

Similar facts as regards intermarriage for mothers are, also, shown: There are 576,597 persons having Massachusetts born mothers; these mothers having married 449,140 men of Massachusetts birth, 79,450 men born in other parts of the United States, and 42,648 men of foreign birth. Of the mothers born in other parts of the United States than Massachusetts, that is, the mothers of 354,388 persons, 83,013 married Massachusetts born men; 243,888 married men born in other parts of the United States; and 25,008 married foreign born men.

#### ON CHRONIC POISONING BY TOBACCO.

At a meeting of the Royal Imperial Society of Physicians of Vienna, held February 18th, Favarger made a communication on the above old, but ever new subject, of which the subjoined is a *résumé*. The symptoms of chronic nicotineism do not generally manifest themselves till after the usage of strong tobacco for ten years or more, and ordinarily follow the free smoking of Havana cigars. As for the manner of smoking, there are four types of smokers:

(1) Those who swallow the smoke; in these cases the nicotine acts probably, directly on the stomach; (2) Those who only breathe in and breathe out the smoke: here the detrimental action remains limited to the pharynx and the larynx; (3) Some smokers keep their cigar constantly between their lips, and are in the habit of swallowing a certain quantity of nicotine mingled with their saliva; (4) There are other smokers who use cigar-holders that are soon fouled with nicotine, and are never properly cleaned.

Chronic poisoning by nicotine manifests itself generally by disturbances of the circulation and digestion. One of the most frequent symptoms is palpitations, then next in the order of frequency is cardiac asthma, and still more rarely occur attacks of angina pectoris. Physical examination of the heart gives sometimes negative results, and sometimes reveals the existence of chronic myocarditis, or of fatty degeneration of the heart. Among the digestive derangements are noted: loss of appetite, pain in the epigastric region, diarrhoea, or constipation. Among the symptoms pointing to disorder of the nervous system are insomnia and attacks of syncope.

Favarger reported a remarkable case of fatty degeneration of the heart in a man aged sixty, who had been for many years an inveterate smoker of strong Havanas. Several weeks before his death, he was attacked after a meal with violent palpitations, and a paroxysm of dyspnoea came on the next day. Till the time of his death, the temperature remained low, (from 34.6° to 36.6° C.); the pulse very frequent and small (140 to 160), and the pupils much contracted. At the autopsy were found pleuritic exudations, dila-

tation, with fatty degeneration of the heart, and an ulcer of the stomach, which had determined a mortal hemorrhage.

In this case, said the reporter, the fatty degeneration of the heart could not be attributed to alcoholism, or any other known cause, except that which was the most obvious, namely, the excessive use of tobacco. This view was confirmed by the abnormal frequency of the pulse, by the great fall in the bodily temperature, and by the contraction of the pupils. Although no arterial atheroma was noted, there existed, nevertheless, in this case a functional stenosis (?) of the coronary arteries, equally attributable to nicotine, and to this constriction of the nutrient arteries of the heart causing ischemia, was due presumably the fatty degeneration of that organ.

As for the ulcer of the stomach, it may have been directly engendered by the topical action of saliva impregnated with nicotine, or it may have been the result of circulatory disturbances, according to the process indicated by Rokitsky and Virchow.

As for the treatment of chronic nicotineism, Favarger recommends as prophylactic means: (1) Never to smoke when the stomach is empty but always after a meal. In this way the number of cigars smoked will be limited, the nicotine will be made to act on a full stomach, loss of appetite will be prevented, and the antidotal ("anti-nicotine") action of the tannin contained in the wine, tea or coffee of the meal will be obtained. Tannin, according to Favarger, is the best antidote to nicotine. (2) Smokers should avoid holding their cigars long in their mouths. (3) Cigar-holders should be frequently renewed, and regularly cleansed. Smokers should smoke the milder cigars occasionally, instead of always choosing the strongest.

According to Erlenmeyer<sup>1</sup> smoking cigars is vastly more injurious than smoking a pipe, because the preparation of tobacco for the latter purpose destroys as much as two-thirds of its nicotine, while the former loses but little of its active principle in the manufacture.

More than twenty-five years ago, Dr. B. W. Richardson presented the following conclusions as the result of an exhaustive study of the effects of tobacco-smoking:

(1) The effects produced are very transitory. (2) The evils of smoking are functional in their character, and statements that it causes insanity, epilepsy, chorea, apoplexy, organic disease of the heart, cancer and consumption, are devoid of fact. (3) The habit of smoking is deleterious to the young. (4) Tobacco is a luxury, but probably the least hurtful of the luxuries. Stillé, in commenting on these propositions, remarks that there are several diseases not enumerated by Dr. Richardson, which excessive smoking unquestionably develops. One of these is amaurosis, many cases of which have been traced to tobacco-smoking by no less competent authorities than Mackenzie and Siebel. "The former, many years ago, hinted his

suspicion that it is a frequent cause of amaurosis, and the latter is now of opinion that there are few persons who have smoked during a long period more than five drachms of tobacco per diem, without having their vision, and frequently their memory impaired." Farnsworth, in the *American Medical Times* (October, 1862), cites a case of impaired vision from the same cause with general anesthesia. "In spite of a well-directed treatment, the disease grew worse until the discovery was made that the patient was in the habit of smoking a pipe almost continually with the coarsest kind of tobacco. On relinquishing this practice he gradually recovered."

### THE LATE AUSTIN FLINT, M.D.

#### IN MEMORIAM.

THIS week, there is to be unveiled, at Bellevue Hospital, New York, a tablet in memory of the late Dr. Austin Flint, which is erected by the Commissioners of Charities and Correction. It consists of a large and massive plate of brass, set in a panel of antique oak, and was made by the Gorham Manufacturing Company. The inscription, which is in Roman letters of black enamel, with initials in red enamel, and surrounded by a band of conventional palm-leaves, relieved, at intervals, with neat scroll work, reads as follows:

#### IN MEMORY OF AUSTIN FLINT, M.D., LL.D.

Entering the profession with broad culture and thorough education, he remained an active physician to the last day of his life. As a medical writer, he added to the knowledge of the American profession and to medical science. As a teacher, he was loved and respected by thousands of his pupils in all parts of the country. As physician to Bellevue Hospital for twenty-five years, he contributed largely to its reputation by his character, acquisitions, labors, and wise counsels.

Erected by the Commissioners of Public Charities and Correction: H. H. Porter, President; Thomas S. Brennan, Charles E. Simmons.

This will be recognized by the profession throughout the country as a well-earned tribute and suitable memorial, at the seat of his later labors, of one of the foremost medical writers, teachers, and practitioners which our country has yet produced—a man whom New England claims as a son.

### MEDICAL NOTES.

—Sir Henry Thompson appeals to the medical public in protest against the use of his name in the advertisements of Friedrichshall mineral water, which he named once in a lecture, twenty years ago, with approval. This was when there were only one or two laxative mineral waters in England, and he no longer endorses the original statement. But the advertisers persist in the use of his name, and he cannot help himself, except by an occasional disclaimer in medical journals.

—The Faculty of Medicine in Berlin has issued a schedule of studies for its students, in which the

<sup>1</sup> Stillé, *Therapeutics*, Vol. II, p. 320.

latter are strongly advised to follow courses in meteorology, mineralogy, geology, anthropology, psychology, and logic. The plan, of course, is not obligatory; but while the Faculty uses no compulsion upon its students in the matter, it holds itself competent to give them good advice.

— Professor Dobroslavine, of St. Petersburg, recommends, as a means of purifying (clarifying?) drinking-water, the addition to each twelve liters of water of fifty centigrammes of perchloride of iron and seventy centigrammes of crystallized carbonate of soda. He claims that the precipitate thus formed carries with it all suspended impurities, leaving the water, after forty-five minutes, perfectly clear.

— The United States Minister at Santiago, under date of January 15, reports cholera as slowly extending along the valley of the Aconcagua, following the course of the river to the sea, near Valparaiso. About 600 cases had been reported up to that date, of which about 250 had proved fatal. The victims were almost exclusively confined to the poorer classes. A dispatch dated February 15th, at Santiago, gave the number of cases from Saturday to Monday noon as 435, and the deaths at 213.

— Dr. J. C. Cutter, a graduate of the Harvard Medical School, and a former house-officer at the Boston City Hospital, who went to Japan in 1878, on a comparatively short contract, as Professor of Physiology and Comparative Anatomy in the Agricultural College at Sapporo, and to act as consulting physician to the former Colonization Bureau (*Kaitakushi*), has had his commission several times renewed; and, it is said, that a proposal to remain until 1889 would have received his assent, had not a pressing message reached him by telegraph from America. The *Japanese Daily Mail* speaks very highly of Dr. Cutter's services at Sapporo, under the Colonization Bureau, the Department of Agriculture and Commerce, and the Hokkaido Administration. In addition to his professional duties, he has done considerable literary work, and two of his books have been translated into Japanese.

— A correspondent of the *Medical Press and Circular* says that in the Highlands of Scotland, as in the Continental Highlands, a belief in miracles, and in incantations and superstitious practices of the grossest nature in curing certain forms of disease, still exists, of which the following incident, occurring the other day at a village on the west coast of Ross, is an illustration: A middle-aged fisherman was seized with a somewhat sharp attack of an eruptive disease, popularly known by the name of shingles, which, according to the local wiseacres, could be cured only by an application of blood drawn from a black cat with a knife or other instrument, with which the umbilical cord of at least seven male children had been divided, and applied with a feather from the wing of a black domestic hen, which had hatched not less than three broods of chickens. To this sanguinary ordeal, the patient, at the solicitations of his friends, agreed to

submit with becoming resignation and unquestioning faith in its efficacy. Having been undressed and laid on his back, with his head toward the south, operator A walked round him three times with the cat, in accordance with the course of the sun. He then held the cat over the patient's breast, while B, with the proper instrument, cropped its right ear, and, as the blood trickled on the sufferer's breast, besmeared it over the affected parts with the feather from the black hen, at the same time muttering incantations in the vernacular. Strange to say, the treatment failed to effect a cure; and, as the patient is still unwell, he is about to undergo a repetition of the performance.

## BOSTON.

— City Physician McCollom, who was deputed by the zealous Boston Board of Health to visit Holyoke, ostensibly to ascertain if the alleged infected foreign rags from which the small-pox was supposed to have sprung were imported through Boston, is said to have made his report, in which he states that there were both foreign and domestic rags in the assortment at the mill where the handlers contracted the disease; the foreign coming by way of New York, the domestic from various localities; but the inspector came to no conclusion as to which was responsible for the infection, the evidence seeming to him negative. This report is quite different from that which appeared in some of the daily papers as being the purport of Dr. McCollom's conclusions; and which appeared, we may say, in advance of any report being made by Dr. McCollom at all. The conclusion is the only one which a sensible and unprejudiced man could reach under the circumstances.

— The lower branch of the Legislature has rejected the bill for Registration of Dentists.

— Prof. Jacob A. Wortman, who is attached to the Army Medical Museum, at Washington, as its anatomist, has been here for some days. He has been deputed by the Surgeon-General's office to study the methods, and examine the recent work at the anatomical laboratory of the Harvard Medical School and the Museum of Anatomy, in common with those of such others as may be likely to offer instructive suggestions for the prosecution of the work at the Washington Museum. This is a well-deserved compliment to the skill and industry of the anatomical department at the Harvard Medical School.

## NEW YORK.

— The police recently arrested no less than sixty-eight Chinese in an opium-joint and gambling den, occupying a tenement on the Bowery.

— The thirtieth annual commencement of the New York College for Veterinary Surgeons and School of Comparative Medicine was held at the Carnegie Laboratory, March 16th.

— The twenty-sixth annual commencement of Bellevue Hospital Medical College took place quietly at the

Carnegie Laboratory, in the evening of March 14th; and after degrees had been conferred on 134 graduates by the President of the College, Dr. Isaac E. Taylor, the Faculty and Class adjourned to Delmonico's, where a dinner provided by the former was enjoyed.

—The Board of Health has amended the section of the Sanitary Code governing the removal of stable-manure, so that, in future, such material on any city premises must either be baled or removed as soon as a cartload has accumulated, it being also provided that the baled manure shall not be allowed to become a nuisance. This change has been made at the request of the Medical Society of the County of New York, on the recommendation of its Committee on Hygiene.

### Miscellany.

#### INTRA-SCROTAL HYDATID CYST.

DR. PHILIP E. MUSKETT, surgeon to the Sidney Hospital, read before the New South Wales branch of the British Medical Association a case of hydatid of the scrotum, which is thus summarized in the *Practitioner*, February, 1887. The patient, a man, aged twenty-five, a native of Lancashire, was brought to Brisbane at the age of three. Swelling of the scrotum began in 1878; it was tapped in 1884, and again within eight months, and iodine injected. In July, 1886, the tumor was painless and transmitted light, and the testicle could be felt at its posterior part. It was tapped with a small trocar; but inflammation ensuing, a larger trocar gave vent to a purulent fluid which continued to drain through the opening; and a membrane, presenting the usual unmistakable characters of a hydatid sac, being grayish in color, translucent and elastic, and in its collapsed condition being such as would about fill an egg-cup, forced its way out and was extracted. The sinus then ceased to discharge, and the scrotum resumed its normal condition.

#### ADMINISTRATION OF GASEOUS ENEMATA.

At a recent meeting of the Philadelphia County Medical Society, in the discussion of some remarks of Dr. J. Solis-Cohen on the "Administration of Gaseous Enemata," Dr. William Osler said that "recently, at the University Hospital, a patient very nearly expired after an injection of a mixture of carbon dioxide and sulphuretted hydrogen. He was not aware at the time that sulphuretted hydrogen, if given in sufficient quantities, is capable of producing poisonous effects, even when taken by the rectum. He mentions this accident, lest similar mistakes should arise. Evidently, the amount of sulphuretted hydrogen which is given must be small. At the Biological Society, at Paris, some experiments were related, which showed that even a few cubic centimeters are sufficient to poison a good-sized dog. In the experiences which are related in French journals, the odor of sulphuretted hydrogen is readily observed in the breath, but this has not been noticed in any of the Blockley patients. This is an exceedingly interesting, not to say comical, method of treating phthisis, but it is too early to say

what the results are likely to be. Certainly, however, in Dr. Bruen's hands, at the Philadelphia Hospital, they have been extremely good."

#### COCAINE-POISONING.

In the *St. Louis Medical and Surgical Journal*, Dr. McIntyre records the following case of cocaine-poisoning: The patient, a well-built man, aged forty, was found, as pale as death, lying on the doorstep of his shop. His pupils were much dilated, and the conjunctiva insensitve; respiration was slow and difficult; the pulse was 140. The patient was unable to articulate, but frequently made signs for water, which was scarcely placed in his mouth when it was rejected, as he could not swallow it. He had fallen into this state owing to a hypodermic injection of three centigrammes of cocaine, twenty minutes before. Dr. Nichols, his ordinary medical attendant, had already, on several occasions, given him hypodermic injections of from three to four centigrammes of this drug, repeating them every half-hour, until twenty centigrammes had been administered; and he was, therefore, much surprised to see one dose produce symptoms of poisoning. The patient was a very intemperate man, and the injection was given as a remedy for the after-effects of drunkenness. Dr. Nichols, who had had a large experience in the use of cocaine for depression following intoxication, said that its effect was to destroy for a time the desire for alcohol. In the present case, the treatment consisted of morphine and alcohol in repeated doses. The patient was in a serious state for some time, but gradually recovered. At the end of four hours he was able to be taken home in a carriage, and fourteen hours after the injection he was quite well.

#### ON THE USES OF BORIC ACID.

DR. J. T. SEARCY in the *Atlanta Medical and Surgical Journal* writes enthusiastically in praise of boric acid, which as an antiseptic, he says, is better than iodoform, besides being cheaper. The best shape in which to use it is as an impalpable powder. Open wounds, before they are closed, may be freely dusted over with this powder, and compound fractures may be so treated, with often the happiest results. No application so effectually destroys the offensiveness of foul sores. Cancerous and other ulcers are benefited by boric acid, in combination with iodoform or not. It makes an excellent injection for gonorrhoeal inflammations, in the strength of ten grains to the ounce of water for the urethra, and half an ounce to the pint of hot water for the vagina. Eczema, both in its moist and in its dry stages, is helped by it, as a rule. Dusted finely on itching surfaces, it proves usually a very grateful application. It is almost a specific for ringworm: moisten the surface first, and with the wet hand, or a piece of sponge, rub the powder into the skin firmly once or twice a day. All itching is soon allayed, and the part gradually gets well. Persons troubled with offensive secretions of the axilla or the feet, will find this a very efficient and safe application. A combination of iodoform one part, boric acid two parts, vaseline four parts, makes an excellent ointment for venereal sores.

## Correspondence.

## REPORT OF MASSACHUSETTS MEDICO-LEGAL SOCIETY. CORRECTION.

NEW BEDFORD, MASS., March 19, 1887.

MR. EDITOR,—Regarding the report of "An Anomalous Arrangement of the Veins of the Neck," in the report of the Massachusetts Medico-Legal Society, on page 262 of No. 11 of the current volume of the JOURNAL, I am informed by Dr. Pinkham that my statement was an erroneous one, as there was no internal jugular vein or other large vein except the vessel occupying the usual site of the external jugular. Will you kindly print this in correction?

Very truly yours,

W. H. TAYLOR, M.D.

## ARSENICAL WALL-PAPERS AGAIN.

BOSTON, March 19, 1887.

MR. EDITOR,—I have been much interested by the recent articles on arsenical wall-paper poisoning, and beg to be allowed to contribute another case which occurred in my own house. Several years ago I had occasion to have my house re-decorated, and having heard a great deal on the subject of arsenic in wall-papers, I was very particular to select none but guaranteed papers. These were furnished by one of our most reliable houses, Messrs. Gregory

& Brown, who showed me certificates of freedom from arsenic, signed by a Mr. Lee, a chemist, who was at that time employed by the firm to make analyses of their papers.

After the completion of the work, one of the bedrooms was occupied nearly two years by a gentleman who constantly complained and particularly in the morning, of not feeling well, but with no very distinct symptoms. The same room was next occupied on two separate occasions by a guest, who each time left the house with undefined illness, which was of sufficient seriousness to warrant consultation with a physician. Another guest was affected in the same way. Still another complained after a few days occupancy, of sore throat, coryza and irritation of the nose and eyes, and headache. A little more than two months ago the room was occupied by my daughter and her infant child. Both were made so ill, particularly the baby, that my daughter cut her visit short in order to get the child home to her husband, who is a physician. It was by him suggested that the secret of the trouble with that particular room might lie in the wall-paper, and I therefore sent a specimen of the paper to Dr. Charles Harrington, of the Harvard Medical School, who reported that it contained a dangerous amount of arsenic.

Messrs. Gregory & Brown on being informed of this fact hastened to do everything in their power to remedy the trouble, insisting on removing and replacing the paper at their own expense. This was done, and since that time there has been no trouble of any sort. In this case the blame rests not upon the dealers but upon the chemist, who, I am informed, is no longer in their employ.

Yours very truly, A. V. S. ANTHONY.

## REPORTED MORTALITY FOR THE WEEK ENDING MARCH 12, 1887.

Northampton . . . . .	12,896	—	—	—	—	—	—	—

Deaths reported 2,471; under five years of age 750; principal infectious diseases (small-pox, measles, diphtheria and croup, diarrheal diseases, whooping-cough, erysipelas and fevers) 316, acute lung diseases 371, consumption 202, diphtheria and croup 131, measles 55, typhoid fever 30, scarlet fever 26, diarrheal diseases 21, cerebro-spinal meningitis 12, puerperal fever 12, erysipelas nine, whooping-cough seven, malarial fevers six. From scarlet fever, New York 12, Brooklyn eight, Philadelphia five, Boston one. From diarrheal diseases, New York 15, Pittsburgh, Charleston, Worcester, Lowell, Chelsea and Haverhill one each. From cerebro-spinal meningitis, New York five, Philadelphia three, Fall River two, District of Columbia and Pittsburgh one each. From puerperal fever, Philadelphia and Boston, three each, Richmond, District of Columbia and Pittsburgh two each. From erysipelas, New York six, Brooklyn, Boston and Somerville one each. From whooping-cough, Brooklyn three, New York two, Richmond and Pittsburgh one each. From malarial fever, New York four, Brooklyn and District of Columbia one each. From small pox, New York one.

In the 21 cities and greater towns of Massachusetts, with a population of 1,041,216 (population of the State 1,941,463) the total death-rate for the week was 20.27 against 18.55 and 20.68 for the previous two weeks.

In the 28 greater towns of England and Wales, with an estimated population of 9,345,099, for the week ending February 20th, the death-rate was 21.3. Deaths reported 3,767; infants under one year of age 836; acute diseases of the respiratory organs (London) 466; measles 140, whooping-cough 94, scarlet fever 41, diarrheal diseases 39, diphtheria 31, fever 21. The death-rates ranged from 13.5 in Nottingham to 33.0 in Huddersfield; Birmingham 18.9; Hull 20.1; Leicester 21.5; Liverpool 24.1; London 20.9; Manchester 20.1; Newcastle-on-Tyne 27.2; Portsmouth 21.9; Sheffield 21.4.

In Edinburgh 21.0; Glasgow 24.9; Dublin 30.7.

The meteorological record for the week ending March 12, in Boston, was as follows, according to observations furnished by Sergeant O. B. Cole, of the United States Signal Corps:—

Week ending	Barometer.	Thermometer.				Relative Humidity.			Direction of Wind.			Velocity of Wind.			State of Weather.			Rainfall.

#### OFFICIAL LIST OF CHANGES IN THE STATIONS AND DUTIES OF OFFICERS SERVING IN THE MEDICAL DEPARTMENT, U. S. ARMY, FROM MARCH 12, 1887, TO MARCH 18, 1887.

CARTER, Wm. F., captain and assistant surgeon. Leave of absence extended four months on surgeon's certificate of disability. S. O. 57, A. G. O., March 11, 1887.

#### OFFICIAL LIST OF CHANGES IN THE MEDICAL CORPS OF THE UNITED STATES NAVY DURING THE MEDICAL PARKING MARCH 18, 1887.

PARKER, J. B., surgeon. Ordered to the United States Steamship "Ossipee."

SIEGFRIED, C. A., surgeon. Ordered to Baltimore, Md., on special duty.

HOGG, JOSEPH, surgeon. Placed on retired list, March 17, 1887.

#### OFFICIAL LIST OF CHANGES OF STATIONS AND DUTIES OF MEDICAL OFFICERS OF THE UNITED STATES MARINE-HOSPITAL SERVICE, FOR THE WEEK ENDING MARCH 12, 1887.

BANKS, C. E., passed assistant surgeon. To proceed to Chicago, Ill., and assume temporary charge of the Service, March 10, 1887.

#### SOCIETY NOTICE.

NORFOLK DISTRICT MEDICAL SOCIETY. — A meeting for Scientific Improvement will be held at the hall of the Roxbury City Guard, 67 Warren Street, Roxbury, March 29, 1887, at 7.45 P.M. Communications: I. "Cases showing Unpleasant Symptoms due to Antipyrin," Edward T. Twitchell, M.D. The discussion will be opened by J. Howard Thurlow, M.D. II. "The Effect of Ether upon the Peripheral Nerves," Henry Bowditch, M.D. A Report of Four Cases of Penetrating Wounds of the Knee-Joint treated at the Boston City Hospital," Oliver H. Howe, M.D., Former House Surgeon.

S. ALLEN POTTER, M.D., Secretary.

#### DEATH.

Died, in East Boston, March 19, 1887, John Beveridge Fulton, M.D., M.M.S.S., aged fifty-two years.

#### RESIGNATION.
